"For the place of growth, that timber is esteemed best which grows most in the sun, and on a dry and hale ground; for those trees which suck and drink little are most hard, robust, and longer lived—instances of sobriety. The climate contributes much to its quality; and the northern situation is preferred to the rest of the quarters; so as that which grew in Tuscany was of old thought better than that of the Venetian side; and yet the Biscay timber is esteemed better than what they have from colder countries; and trees of the wilder kind and barren, than the over much cultivated and great bearers."

Dr Parry has published an excellent paper on the causes of the decay of wood, and the means of preventing it. From it we take the liberty of abridging what follows; but would recommend a careful perusal of the whole of it to those who wish for further information on the subject.[*]

Decay.

Wood Dr Parry supposes to be subject to destruction from two causes, rotting and the depredations of insects. Of rot there are two supposed kinds, the first takes place in the open air; the second under cover.

When perfectly dry, and in a certain degree of temperature, both animal and vegetable matters seems scarcely capable of spontaneous decay. On this principle, fish and other animal matter is often preserved.

"Similar causes produce the same effects on wood. Even under less rigid circumstances of this kind, as in the roofs and other timber of large buildings, it continues for an astonishing length of time unchanged. Witness the timber of that noble edifice, Westminster-hall, built by Richard II. in 1397; and the more extraordinary instance quoted by Dr Darwin, in his ingenious work the *Phytologia*, of the gates of the old St Peter's church in Rome, which were said to have continued without rotting, from the time of the Emperor Constantine to that of Pope Eugene IV. a period of eleven hundred years. On the other hand, wood will remain for ages, with little change, when continually immersed in water, or even when deeply buried in the earth, as in the piles and buttresses of bridges, and in various morasses. These latter facts seem to show, that if the access of atmospherical air is not necessary to the decay of wood, it is at least highly conducive to it."

Putrefaction.

Putrefaction is the cause of rotting, and putrefaction is occasioned by stagnant air and moisture. The moisture of the air, coming in contact with wood of a lower temperature, is condensed in the same manner, as is more visible in our glass windows. In order to prevent the bad effects of this condensation, currents of dry air ought to be made to pass in contact with the timber. Of the advantages of this, the Gothic architects seemed aware; for it was common with them to leave openings for this purpose—a practice which we could strongly recommend in cellars, &c.

"It appears that the contact of water and air are the chief causes of the decay of wood. If, therefore, any means can be devised, by which the access of moisture and air can be prevented, the wood is so far secure against decay. This principle may be illustrated, by supposing a cylinder of dry wood to be placed in a glass tube or case which it exactly fills, and the two ends of which are, as it is called, hermetically sealed, that is, entirely closed, by uniting the melted sides of each end of the tub. Who will doubt that such a piece of wood might remain in the open air a thousand years unchanged? Or let us take a little more apposite illustration of this fact, that of amber, a native bitumen or resin, in which a variety of small flies, filaments of vegetables, and others of the most fragile substances, are seen imbedded, having been preserved from decay much longer probably than a thousand years, and with no apparent tendency to change for ten times that period."

These observations lead to the theory of painting timber, for the purpose of preserving it.

Dry rot.

Mr Batson of Limehouse is of opinion, that the dry rot proceeds from a plant, called *Boletus Lacrymans*, one of the fungus tribe, and is one of the few that have leaves as the misletoe. But Dr Parry justly observes, that these plants "*begin merely, because decayed wood is their proper soil.*"

"The smell which we perceive in going into vaults or cellars, where this process is going on, arises partly from the extrication of certain gases, mingled perhaps with some volatile oil, and partly from the effluvia of those vegetable substances, which have already been said to grow on it, and which, though they begin *merely because*

---

[*] Papers of Bath and West of England Society, vol. xi. p. 226.; also Nicholson's *Journal*, No. 85, 86, and 87

the decayed wood is their proper soil, yet afterwards tend probably to the more speedy decomposition of the wood itself.

"The following, then, appears to be the whole theory of the dry rot, that it is a more or less rapid decomposition of the substance of the wood from moisture, deposited on it by condensation, to the action of which it is more disposed in certain situations than in others; and that this moisture operates most quickly on wood, which most abounds with the saccharine or fermentable principles of the sap." Thus far Dr Parry.

Charring. Charring of wood is known to be a most effectual mode of preservation against rotting.

The incorruptibility of charcoal is attested by numerous unquestionable facts. At the destruction of the famous temple at Ephesus, it was found to be erected on piles that had been charred; and the charcoal in Herculaneum, after almost 200 years, was entire and undiminished.

To this property of charred wood Sir C. Wren does not seem to have attended, when about to build St Paul's. It is said, he thought piles were not to be depended on for a foundation, excepting when always wet; and therefore dug to a great depth through a dry soil, in order to come at a solid foundation for part of that cathedral. See Wren's *Parentalia*.

Charcoal. Charcoal has also been found useful as a defence to the surface of wood when used as a paint. We lately had a good instance of the effect of sand used for this purpose. At Studly Royal we saw a temple to appearance of stone, but which on examination we found to be wood covered with paint, and dusted over with sand. We were informed it had stood about 50 years; and the deception was still so complete, that the spectators supposed the pillars to be stone, till minutely examined.

Stone. From *marble* being plentiful in Italy and France, these countries have been able to make a considerable use of it, even in the main walls of their edifices; but being seldom found in sufficient quantities, and of proper quality, in the more northern parts of Europe, it has been here chiefly confined to interior columns, pavements, chimney-pieces, and sometimes stairs.

The kinds of *stone* are as various, as the countries in which the buildings are constructed. *Sandstone* being very generally found stratified, even in thin laminæ, being readily cut into different forms, and being, if properly selected and used, sufficiently durable, it has, in northern countries, been in most frequent use. It is a general accompaniment of coal strata, and is also often found where the latter does not occur. It varies in its component parts, being at different places argillaceous, siliceous, and calcareous. Its position, in the earth, assumes all directions, from the horizontal to a vertical plane. The proportional thickness of its strata, laminæ, or beds, varies from that of thin slate to many feet each. The upper beds are usually very thin or soft, or both; if sufficiently hard, they are employed in floor pavements and covering roofs. Under these the beds generally, in useful quarries, increase in thickness, hardness, and tenacity. The position of the laminæ always require strict attention, that the worked stone may, if possible, be laid in the building upon its natural bed; for although some instances occur, as in the Isle of Portland and at Grinshill, in Shropshire, where the difference is not apparently great, yet in all stone (even granite) it is sufficiently well known to workmen. Some stone, as that of Bath, is so soft when taken out of the quarry, as to be very conveniently worked with tools resembling those used by carpenters; yet when exposed for some time to the atmosphere, it becomes hard and durable. This last, indeed, cannot be deemed sand stone, being nearly altogether calcareous.

Stone from Tottenhoe. Besides the before mentioned, there is a very beautiful stone, dug in the hills near Dunstable, in the parish of Tottenhoe, from whence the stone receives its name. It has the appearance of indurated chalk. It is easily worked, and hardens by exposure to the weather. It should, however, be placed upon a plinth of some other stone, or kept by other means from contact with the ground, otherwise it is, in this situation, liable to be injured by the frosts. The house of the Duke of Bedford, at Woburn Abbey, is built chiefly with this stone, and various other large houses in the neighbourhood of the quarries. Proofs of its durability may be seen in many old churches. From the closeness of its texture, the beauty of its colour, and the facility with which it is worked into mouldings, &c. it is peculiarly fit for house-building, both externally and internally. It may now readily be conveyed to London, by means of the Grand Junction Canal.

The very perfect preservation of many beautiful churches in the counties of Lincoln, Rutland, and Northampton, are evidence of the excellence of the stone of which they are built.

Stone in Scotland. In the central parts of Scotland, different varieties of sandstone, which accompany coal, are used extensively in building houses, &c.; and this circumstance has not a little contributed to the fine appearance of the new streets, squares, and public buildings in the cities of Edinburgh and Glasgow.

Flints. Flints, where they abound, and where other stone is scarce, are sometimes used in walls of considerable height; and notwithstanding their small size, and irregularity of shape, are broken so as to compose a face of considerable smoothness. The church and steeple of Rickmansworth, in Hertfordshire, affords a fine specimen of this kind of building. But bricks or squared stones are generally used as quoins for this sort of work.

Granite. In Scotland and Sweden granite is made use of as a building material. It lies in large masses, generally separated by gunpowder into moderate, though still large dimensions, which are again cut into suitable scantlings, by means of iron instruments called plugs and feathers. They are not only worked into plain square forms, but also mouldings of considerable delicacy, by means of pointed tools of different sizes and weights. **Aberdeen granite.** At Aberdeen, in Scotland, where excellent granite is produced, and the working of it brought perhaps to the greatest perfection, there are handsome porticos, consisting of columns, bases, caps, and entablatures, executed in granite with great nicety. In the middle of the city a public building, whose front is composed of a full Doric order, is wholly completed with this excellent material. There are two sorts of granite, the one grey and the other red; the last being the hardest, is most difficult to work, consequently the former is most frequently employed; it consists of feldspar, mica, and quartz. It is much employed for paving the carriage way of streets, and in the curbing of the flat side pavements; also for piers and footpaths of bridges; and for facings and copings to quays and wharfs. At Aberdeen, it is employed in constructing very extensive piers, for protecting the entrance of the harbour; and in the Eddystone and Bell-Rock light-houses, it composes the facings, where they are exposed to the action of the sea.

Whin. *Whin*, *basalt*, and *schistus*, are also used in rubble work. The former dressing freely with the hammer, in one direction, may readily be formed with good faces, but not being stratified, their beds are uncertain, and not easily improved by art; the latter, that is schistus, is just the reverse, having naturally good beds, but being, in few instances, willing to dress square across the laminæ: They are, indeed, where expence is not an object, worked to a face by the laborious operation of striking perpendicularly with a wedge-mouthed hammer or stone-axe: Both kinds are laid, sometimes promiscuously, and at others in regular courses.

Limestone. *Limestone*, where found regularly stratified, affords good building stone, and combines the advantages of both the former, having naturally good beds, and dressing readily for a face.

Schistus. A species of schistus stone affords a covering to roofs totally unknown to the ancients, and which, when good of its kind, and properly prepared and laid on, is both very effectual and beautiful; it is, in those northern climates, an object of sufficient importance to require to be treated more at length than can, with propriety, be done in the present Section; so that we must refer the reader to the word SLATE for farther information.

Bricks. *Bricks* have, in England, become a material very generally employed in constructing all kinds of buildings. The country is provided by nature with abundant supplies of coal for burning bricks, which can, by means of the sea or numerous inland navigations, be, with great facility, conveyed to the large towns and populous districts where the demand has long been very great. Clay of proper quality is usually found, either upon the spot or immediate vicinity; a very limited number of workmen, properly arranged, can manufacture a great number of bricks in a stated time; these can readily be removed to the place where they are to be employed; being light to handle, and of a rectangular shape, the workmen lay them with facility and ease. By means of bricks, walls can be made much thinner than with almost any kind of stone, they are therefore cheaper, and occupy less space; in forming doorways, windows, chimneys, apertures and angles of all kinds, the facility they afford is greater than that of any other durable material. A building, whose walls are made with bricks, dries soon, is free from damp; and, if properly made, and thoroughly well burnt, bricks endure equal to most, and longer than many kinds of stone. The best modes of manufacturing them having already been so fully discussed, in this work, under the word BRICK, it would be superfluous to repeat them.

Tiles. *Tiles* have long been employed in England for covering the roofs of buildings situated in towns, and of farm houses and cottages in the country, but of late years the use of them has been much circumscribed by the extension of that of slates; the particular mode of manufacturing and using them, will be found under the word TILE.

Sand. Respecting *sand*, the ancient and modern practice agrees nearly in all that need be said; that which is of angular shape, hard texture, and perfectly free of earthy particles, is admitted to be best. The circumstances necessary to be attended to in employing it, have already been mentioned in the article BRIDGE.

Lime. *Lime*, as employed in mortar, has already been investigated and explained under the article BRIDGE. What regards the practical operations of quarrying and burning, will be found under the words LIME, and LIMEKILN.

Metals. In regard to *metals* in modern times, the use of *copper* and *bronze* has, in building purposes, been mostly abandoned. *Brass* has been continued in locks, pullies, sash-windows, handles, and sliding plates, connected with bells, and sundry other purposes in fitting up the interior of apartments. *Iron* has been applied to many purposes unthought of in former times. The improvement and general introduction of cast iron bids fair to create a totally new school of architecture. It has already been occasionally employed in pillars, roofs, floors, chimney, doors, and windows; and the facility with which it is moulded into different shapes, will continue to extend its application. The before-mentioned purposes, to which it has already been applied, will be more particularly noticed in the discussions of Practice in the different Branches of Architecture; and an investigation of the qualities of the material itself, as well as the mode of procuring and manufacturing it, will form a separate and important head under the word IRON.

Glass. *Glass*, as a building material, was little if at all known to the ancients, and its introduction alone has been productive of comforts and elegancies to which the most refined of the Greeks and Romans were utter strangers. Their oiled paper, transparent horn, talc, shells, and linen, would now, even to an English peasant, appear a miserable expedient. An account of the application of glass in architectural works, will frequently occur as we proceed through the several branches; but being also extensively employed in purposes totally distinct from what is connected with buildings, we must, for a general and full investigation of it, refer to the word GLASS.

Hair. Papers. Besides the materials which have already been enumerated as composing the principal members, as walls, roofs, floors, doors, windows, chimneys, stairs, and pavements; hair is also necessary in the composition of mortar for plastering the surface of the walls and ceilings; likewise various paints and papers for covering them and other parts of the work; but as these will be described, and the modes of applying them explained in their proper places, it would be improper to swell this article by entering upon the subject at present.

Definitions relating to the Orders.

Orders: Egyptian. Greeks. The moderns have applied the term *order* to those architectural forms with which the Greeks composed the façades of their temples. The principal members of an order are, 1. A platform; 2. Perpendicular supports; and, 3. A lintelling or covering connecting the tops of these supports, and crowning the edifice. The proportioning these parts to the edifice and to each other, and adapting characteristical decorations, constitutes an order, *canon*, or *rule*. We have already seen that the Egyptians employed all the principal members of an order, and also in some instances adapted very fine decorations, but they never varied the general character,—it continued uniformly to express dignified gravity. The Greeks, in the spirit of freedom, and with peculiar facility of invention, varied the expressions of their architecture as well as sculpture, and produced three species, which are denominated orders. The principal member of an order,

Column. is the perpendicular support or column. The accompaniments being subservient to this leading feature, the bottom of the column is placed either on a general artificial platform, or each upon a particular plinth, or both. The lower part of the column, which rests upon the square plinth, is sometimes encompassed with mouldings, which, in allusion to their position, are, in conjunction with the plinth, termed a *Base*. The top part of the column is also Base. covered with a square plinth, with its sides straight or curved, and generally accompanied by circular mouldings or sculptured decorations upon the top part of the column which is immediately underneath it: this, taken together, Capital.

Entablature.

Doric first Greek order.

is called the Capital. The body of the column, which reaches between the base and capital, is termed the Shaft: it is the frustrum of a cone, with sometimes a plain surface, but frequently having perpendicular flutings either meeting in an edge. or leaving a small plane space between them. The lintelling or covering, which lies upon and connects the columns, is termed the Entablature, and is sub-divided into three parts, named Architrave, Frieze, and Cornice: The architrave consists of a mere lintel laid along the tops of the columns; the frieze represents the ends of the cross beams resting upon the former, and having the spaces between filled up, having also a moulding fixed to conceal the horizontal joint, and divide it from the architrave; and the upper member or cornice represents the projecting eaves of a Greek roof, shewing the ends of the rafters. The whole is distinctly exemplified in the first Greek or Doric order; the earliest instances of which exhibit Egyptian character, and proportions adapted to the climate and materials of Greece; the column of the Doric being as gross in proportion to its height as the pillars of the Thebaid; but Greece being subject to rains, it was found necessary to elevate the whole edifice on an artificial platform, and cover it with a pointed roof, having projecting eaves, thus constituting features totally different from Egyptian. The three Greek orders, named Doric, Ionic, and Corinthian, have the same principal members, and subdivisions, but the dimensions, mouldings, and decorations, vary very considerably, as will be seen by the specimens of each, which will, in the course of this investigation, be produced.

It is only in Greece, or in the territories of Greek colonies, that pure specimens of these orders have been found. Their mouldings exhibit every specimen of conic section, as elliptical, parabolical, hyperbolical; some are merely champhered: the circle was seldom employed excepting in small cavettos and mouldings of contrary flexures.

Mouldings.

Mouldings.

Section.

Mouldings are prismatic or annular solids, formed by plain and curved surfaces, and employed as ornamental parts in most architectural operations: All parallel sections of straight mouldings, and all sections passing through the axis of annular mouldings, are equal similar figures; the forms of all mouldings are referred to a section at right angles to their longitudinal direction, when prismatic, or passing through the axis, if annular; and this is simply denominated *the Section*, on account of its frequent use, as oblique sections only occur in mitres. The names of mouldings depend upon their form and situation.

Names and shapes.

If the section is a semicircle which projects from a vertical diameter, the moulding is called an Astragal, Bead, or Torus; if a torus and bead be both employed in the same order of architecture, they are only distinguished by the bead being the smallest. The tori are generally employed in bases, but the bead both in bases and capitals.

If the moulding be convex, and its section be the quarter of a circle or less, and if the one extremity project beyond the other equal to its height, and the projecting side be more remote from the eye than the other, it is termed a Quarter Round; this, in Roman architecture, is always employed above the level of the eye.

If the section of a moulding be concave, but in all other respects the same as the last, it is denominated a Cavetto. They are never employed in bases or capitals, but frequently in entablatures.

Names and shapes of mouldings.

If the section of a moulding is partly concave and partly straight, and if the straight part be vertical and a tangent to the concave part, and if the concavity be equal or less than the quadrant of a circle, the moulding is denominated an Apophyge, Scape, Spring, or Conge: it is used in the Ionic and Corinthian orders for joining the bottom of the shaft to the base, as well as to connect the top of the fillet to the shaft under the astragal.

If the section be one part concave and the other convex, and so joined that they may have the same tangent, the moulding is named a Cymatium; but Vitruvius calls all crowning or upper members cymatiums, whether they resemble the one now described or not.

If the upper projecting part of the cymatium be a concave, it is called a Cima-recta, they are generally the crowning members of cornices, but are seldom found in other situations.

If the upper projecting part of the cymatium be convex, it is called a cima-reversa, and is the smallest in any composition of mouldings, its office being to separate the larger members: it is seldom used as a crowning member of cornices, but is frequently employed with a small fillet over it, as the upper member of architraves, capitals, and imposts.

If the convex part of a moulding recede and meet a horizontal surface, the recess formed by the convexity and the horizontal surface is termed a Quirk.

If the section of the moulding be a convex conic section, and if the intermediate part of the curve project only a small distance from the greatest projecting extremity, and if the tangent to the curve at the receding extremity meet a horizontal line produced forward without the curve at the upper extremity, the moulding is called an Ovolo. It is generally employed above the eye, as a crowning member in the Grecian Doric. Ovolos may be used in the same composition of different sizes; it is sometimes cut into egg and tongue, or egg and dart, when it is termed Echinus. It is employed instead of a torus in the base of Lysicrates at Athens. The contour of ovolos are generally elliptical or hyperbolical curves. These curves can be regulated to any degree of quickness or flatness; the parabola can also be drawn under these conditions, but its curvature does not afford the variety of change of the other two species.

If the section be a concave semi-ellipse, having its conjugate diameter such that the one may unite the extremities of its projections, and the other diameter may be parallel to the horizon, the moulding is termed a Scotia. They are always employed below the level of the eye; their situation is between two tori. The one extremity has generally a greater projection than the other, and the greater projection is nearest to the level of the eye.

If the section of the moulding be the two sides of right angles, the one vertical, and the other of course horizontal, it is termed a *fillet, band*, or *corona*. A fillet is the smallest rectangular member in any composition of mouldings. Its altitude is generally equal to its projection; its purpose is to separate two principal members, and it is used in all situations under such circumstances. The corona is the principal member of a cornice. The beam or facia is a principal member in an architrave as to height, but its projection is not more than that of a fillet.

Rules for describin moulding

In the following descriptions, the projections and heights are always supposed to be given in position to the extremities of the curve.

Torus. Plate CLXXXII Fig. 1.

To describe the *torus*, Plate CLXXXII. Fig. 1. Let ab be the vertical diameter whence the torus projects; bisect ab in c; from c, with the radius ca or cb, describe the semicircle bda, which will be the profile of the torus.

Ovolo.

To describe the *ovolo*, the height and projection being

Plate CLXXXII. Fig. 2. No. 1. and 2.

given Fig. 2. First, let the height and the projection be equal to each other. Draw *ab* equal to the height, and *bc* at a right angle with, and equal to, *ab*, for the projection; then with the radius *ba* or *bc* describe the arc *ac*, which is the contour of the ovolo. But if the projection is not equal to the height, but less, as in Fig. 2. draw *ab* and *bc* forming a right angle as before, *ab* being made equal to the height, and *bc* equal to the projection; from the point of recess *a*, with the height *ab*, describe an arc *bd*; and from the point *c* of projection, with the same radius, describe another arc cutting the former at *d*; lastly, from *d*, with the radius *da* or *dc*, describe the arc *ac*, which is the contour required.

Cavetto. Fig. 3. 4.

The methods of describing the *cavetto*, Fig. 3. and 4. are the same as that for describing the ovolo, the one being the same as the other reversed.

Cima-recta. Fig. 5.

To describe the *cima-recta*, Fig. 5. Join the point of recess *a* to the point of projection *b* by the line *ab*; bisect *ab* in *c*, with the distance *bc* from the points *c*, *b*; describe the intersection *e*, and from the points *ac*, with the same distance, describe the intersection *d*; from *d*, with the distance *da* or *dc*, describe the arc *ac*; and from *e*, with the distance *eb* or *ec*, describe the arc *bc*; and *acb* will be the contour of the cima-recta required. If the curve is required to be made quicker, we have only to use a less radius than that of *ac* or *cb*, in order to describe the two portions of its contour.

Cima-reversa. Fig. 6.

The same description applies to the *cima-reversa*, Fig. 6. by the same letters of reference.

Apophyge. Fig. 7.

To describe the *apophyge*, Fig. 7. the projection being given. Let *ab* be the projection, and *ace* a line which it is required to touch. Make *ac* equal *ab*, and with the distance *ac* or *ab* from the points *b* and *c* describe the intersection *d*; from the point *d*, with the radius *db* or *dc*, describe the arc *bc*, which is the contour of the apophyge.

Fig. 8.

To describe the *apophyge* so as to touch a right line given in position at the point of projection, Fig. 8. Let *bc* be the right line; and *ab* the projection of the moulding; draw *acdf* at a right angle with *ab*; make *cd* equal to *cb*; draw *be* perpendicular to *bc*, and *de* perpendicular to *cd*; from the point *e* describe the arc *bd*, which is the contour of the moulding.

Scotia. Fig. 9.

To describe the *scotia*, Fig. 9. the extremities *a* and *b* of the curve being given. From the projecting point *b* erect *bde*, and from the receding point let fall *agc* perpendicular to *bc*, the horizontal of the moulding; add the half of *ac* and two-thirds of *be* into one length, which set from *b* to *d*; from the centre *d*, with the distance *db*, describe the semicircle *bfe*; draw the straight line *eaf*, and *dgf*; from the point *g*, with the distance *ga* or *gf*, describe the arc *af*: then will *afb* be the contour of the scotia required.

Greek ovolo. Fig. 10. 11.

To describe an *ovolo*, the tangent *ac* at the receding extremity *a*, and its projection at *b* being given, Fig. 10. and 11. Draw the vertical line *cbd*; draw *be* parallel to *ca*, and *ae* parallel to *cb*; produce *ae* to *f*, making *ef* equal to *ea*; divide *eb* and *bc* each into the same number of equal parts; from *f*, and through the points of division in *ab*, draw right lines; also from *a*, and through each of the divisions in *bc*, draw another system of lines, and the corresponding intersections of each pair of lines will be as many points in the curve as there are pairs; then a curve being drawn through the points, will be the greater part of the contour. The remaining part *bg* may be found in the same manner, by drawing lines from *a* through the points in *be* instead of *f*, and drawing lines from *bd* to *f*, instead of *bc* to *a*. The curve drawn in this manner is a portion of an ellipsis, something greater than the quarter of the whole. The recess of the moulding at its projecting point is denominated the quirk. Fig. 10. is adapted for entablatures; and Fig. 11. having a large projection, to capitals of Doric columns, such as may be seen in the temple of Corinth, and in the Doric portico at Athens. This method, though easy, gives the extremity of the conjugate axis, between the receding extremity *a*, and the point of projection *b*; but the following method gives the extremity of the shorter axis, where the tangent commences, at the receding extremity of the contour of the ovolo.

Plate CLXXXII. Fig. 12.

To describe the *ovolo*, supposing the extremity of the conjugate axis to be at the point of contact *a*, Fig. 12. Join *ab*, which bisect in *e*, and draw *cef*: make *aflk* perpendicular to the tangent *ac*, then the point *f* will be the centre of the ellipsis: draw *fhi* parallel to *ac*; take the distance *fa*, and from the point *b* cross the line *fi* at *h*; produce *bh* to *l*, and make *fi* equal to *bl*; then with the semi-transverse *fi*, and the semi-conjugate *fa*, describe an ellipsis, and the portion of the curve contained between the extremities *a* and *g*, will be the contour of the moulding required. This method is recommended as producing the most graceful form of an ovolo, as the lower extremity of the curve begins at the point of contact. From the large projection here given, the moulding is adapted to Doric columns.

Fig. 13.

To describe the *hyperbolical ovolo*, as used in Doric capitals, the same things being given as before, Fig. 13. Erect *adefg* perpendicular to the horizon, and draw *cd* and *be* at right angles to *adefg*: make *eg* equal to *ae*, and *ef* equal to *ad*; join *bf*, divide *bf* and *bc* into the same number of equal parts, and draw lines from g through the divisions of *bf*, also lines from *a* through the divisions of *bc*: Each corresponding pair meeting as before, will give the points in the curve of the hyperbolical moulding. This is the general form of the ovolos in the capitals of the Grecian Doric.

Fig. 14.

To describe a *scotia*, Fig 14. Join the extremities *a* and *b* of the moulding; bisect *ab* in *c*; draw *ecd* parallel to the horizon; make *cd* equal to the recess of the curve, and *ce* equal to *cd*; then with the conjugate diameters *ab* and *ed* describe the curve *adb*, which will be the contour of the moulding required.

Annulets. Fig. 15.

Fig. 15. represents the form of the annulets as applied in Fig. 13. where the receding parts are in the tangent at the bottom of the curve of the ovolo.

Fig. 16.

Fig. 16. represents another kind of annulet, which has a vertical position. This form is only to be found in the Doric portico at Athens.

Fig. 17.

Fig. 17. represents a curious Grecian moulding, to be found under coronas.

To diminish columns. Plate CLXXXIII. Fig. 1.

To diminish the shaft of a column, Plate CLXXXIII. Fig. 1. Let AB be the altitude of the column, and BC the diminution at the upper end of the shaft; divide AB into any number of equal parts, and divide the projection BC into the same number; draw the lines 1*b*, 2*d*, 3*c*, &c. at right angles to the altitude; and draw other lines from the points 1, 2, 3, &c. in BC towards A, to intersect with the former parallel lines at the respective points *b*, *c*, *d*; then A*bcdef*C, will be the curve line of the section of the column.

Fig. 2.

But suppose it were required to give less swell to the column, as in Fig. 2. Divide AB as before, and DC into two equal parts at D; divide DC into as many equal parts as AB; then proceed as in Fig. 1.. Or thus: suppose EF to be the axis of the column, EG, EA the semi-diameters at the bottom, and FN, FC the semi-diameters at the top; on AG, as a chord, describe the segment AOPG of a circle, proportionably less than a semicircle, as the swell is intended to be less; draw NP parallel to FE; divide the arc GP into any number of equal parts, and divide the altitude EF into the same number of equal parts: through the points of division draw the lines $a\,h$, $b\,i$, $c\,k$, $d\,l$, $e\,m$, parallel to AG; also draw G $1h$, $2i$, $3k$, $4l$, $5m$, PN, perpendicular to A; then through the points G, h, i, k, l, m, N, draw a curve, which will be the contour required.

Flutings. PLATE CLXXXIII. Fig. 3.

To describe the flutes of a column without fillets, Fig. 3. Let AB, No. 1. be the diameter, which bisect in G; draw AD and BC perpendicular to AB, and describe the semicircle AEFB; draw DC to touch the circle, and DEG and CFG to the centre G; divide the arc EF into five equal parts, and run the same part on the arcs EA and FB, so that the whole will be divided into nine equal parts, and two half parts at each extremity; then the points of division will mark the arris of the flutes. Their concavity will be found by an arc described from the summit of an equilateral triangle. The fluting at the upper end of the shaft, shown in the concentric circle, is described in the same manner. No. 2. represents the bottom elevation, and No. 3. the top elevation of the shaft, as drawn from the section.

No. 2. No. 3.

Fig. 4.

To describe flutes with fillets on the shaft of a column, Fig. 4. Supposing every thing is done as in Fig. 3. before the division of the circle. Divide EF into six equal parts, and run the chord upon the arcs EA and FB, each of which will contain it three times, so that the whole semicircumference will be divided into twelve equal parts, the points of division marking the centres of the flutes: divide the chord of one of these small arcs into five equal parts; then with three of these parts as a radius, from each of the aforesaid centres describe a semicircle, which will be that representing the section of the flute. Those of the interior circle representing the top of the shaft, are found by drawing the lines to the centre, as appears sufficiently by the figure. No. 2. the elevation of the fluting at the bottom of the shaft, as in the temple of Vesta at Rome. No. 3. the elevation of the fluting, as in the temple of Bacchus at Teos. No. 4. and 5. the common way in which the flutings of columns are terminated at the bottom and top of the shaft.

No. 2. No. 3. No. 4. 5.

Of the Doric Order.

Doric order. PLATE CLVIII.

This is the most ancient of the three orders, (see Plate CLVIII.) and, while employed by the Greeks, was without a base; the surface of its shaft is usually found worked into twenty very flat flutes, meeting each other at an edge, which is sometimes a little rounded; the upper member of the capital is a square abacus or thin plinth, under which is a large and elegantly formed ovolo, with a great projection; immediately under the ovolo, there are three fillets or annulets which project from the continued line of the under part of the ovolo, and have equally recessed spaces betwixt them; the flutings of the column are terminated by the under side of the last of these fillets, and either partly or entirely in a plain surface at right angles with the axis of the column.

Detailed description. Shaft and capital.

Architrave.

The architrave is composed of one vertical face, with a band or fillet at its upper edge; to the under side of this band are suspended a small fillet and conical drops or guttæ, which, for their position, are dependent upon the ordnance of the frieze.

Frieze.

The frieze consists of rectangular projections and recesses placed alternately. The height of each projection or tablet is rather more than its breadth. The recesses are either perfectly or nearly square. The tablets are each cut vertically into two angular channels, with two half ones on the extreme edges; each channel is formed by two planes meeting at its bottom at a right angle, and each forming an angle of 135 degrees with the face of the tablet. The upper ends of the channels are terminated in various forms; the tablets are, from their channellings named Triglyphs; in a direction immediately under each triglyph, and equal to its breadth, a small fillet is attached to the lower side of the architrave crowning band, and from it depend six guttæ or drops, which are generally the frusta of cones with their bases downwards, though they are sometimes of a cylindrical shape. The square spaces in the frieze between the triglyphs, are named Metopes, and are frequently decorated with sculptures.

Cornice.

The cornice is strongly marked by a corona of great projection, forming a very distinct separation between its upper and lower parts; and by having, below the corona, and immediately over the triglyphs, blocks named Mutules, which also project considerably, and have the plane of their soffits with an inclination from their roots towards the horizon, and these have likewise guttæ or drops depending from their soffits.

That the proportion which the different members of the Doric order bore to each other were practised by the Greeks with considerable latitude, will be evident from the following Tables, which exhibit the dimensions of the principal parts of this order in all the ancient Greek edifices which have been examined with accuracy. The dimensions here put down are in feet, inches, and decimal parts.

Observations upon the above Tables.

In the temples of Jupiter Panellenius at Ægina, Theseus at Athens, Minerva at Sunium, Jupiter Nemeus between Argos and Corinth, the cornice has lost the ovolo or crowning member, the dimensions in the table are therefore taken without it; the temple of Minerva Parthenon at Athens is the only ancient Greek edifice in which this member exists, and in this instance the lower extremity is recessed within the fillet which is immediately under it. Those parts marked with a star in the table are totally gone. The crowning member of the cornice of the portico of Philip King of Macedon is a cima recta, having its lower extremity also recessed within the fillet which is below it. The cornice of the hexastyle temple of Pæstum is crowned with a cavetto. Being a singular circumstance in the Greek Doric, it leads to a suspicion that it may have been added in some subsequent repair.

From consulting these Tables, it will be seen, that in the best examples, the height of the architrave and frieze are nearly equal; in the temple of Sunium they are precisely so. The only exception of consequence is in the temple of Juno Lucina at Agrigentum, where the architrave exceeds the frieze 9½ inches: in no other instance is the difference at all material, and any that does exist has most probably arisen from the impracticability of procuring so many marbles of the same dimensions. In comparing the tabular dimensions, it is to be observed, that the band or capital of the triglyph is included in the height of that member. This, in Stuart's *Athens* and the *Ionian Antiquities*, projects only in front, but never returns upon the flanks but at the external angle of the edifice. With the exception of the Doric portico and the temple of Jupiter Nemeus, where the heads of the glyphs are terminated by planes parallel with the horizon, the middle part of the beads, in all the purest examples, is a horizontal plane, and the surface of the sides cylindrical, so as to form a tangent with the intermediate plane, and likewise the arc on the face a tangent with the intersection of each vertical plane of the glyph. Each semiglyph is terminated by two semi-cylindrical surfaces, the axis of each cylinder being perpendicular to each return of the glyph, and thereby forming a semi-cylindric groin, and a pendent with each angle above the semiglyph. The general height of the epistyle or architrave is equal to the superior diameter of the column, though in some cases a little more or less; the height of the zophorus or frieze is equal to that of the epistyle; the mean breadth of the triglyph tablet is equal to half the inferior diameter of the column; the mean height of the cornice is half the diameter; so that the architrave, frieze, and cornice, are respectively to each other as the numbers 3, 3, and 2. If the whole entablature is divided into 8, the breadth of the triglyph is two of these parts.

In all examples of this order, except the temple of Apollo at Delos, the hexastyle temple at Pæstum, the portico of Philip king of Macedon, and the Doric portico at Athens, the face of the triglyph tablet, and that of the epistyle or architrave, are in one vertical plane; so that the fillet named regula, and the gutta under the cup of the epistyle, being regulated by the breadth of the triglyph, will, at each external angle, only touch at their internal points, and leave a void space at the external angle of the epistyle cups. This is exemplified in the temples of Minerva, Theseus, and the propylea at Athens; the temple of Minerva at Sunium; Jupiter Nemeus, Jupiter Pannellenius, Minerva at Syracuse; Concord at Agrigentum; the hypethral temple at Pæstum, and also of Silenus and Jupiter at the same place. And where the face of the epistyle, and that of the triglyph tablet, are in one vertical plane, the guttæ will be six in number under each regula, at every external angle or return, that is, making twelve on the two sides. In the Doric portico at Athens, the temple of Apollo at Delos, and the hexastyle temple at Pæstum, the face of the metopes and that of the epistyle are in one vertical plane. The triglyphs, regula, and guttæ, project from the plane of the epistyle, and at the returns meet at the external angles; and though the guttæ appear six on each face, yet the guttæ at the angle being common to both faces, the whole make only eleven.

In the cornice, the corona forms the most prominent feature in the temple of Concord at Agrigentum, and of Jupiter at Silenus. Instead of having the crowning ovolo, the cornice terminates with a face receding within the corona. This is so contrary to usual practice and propriety, that we are led to suspect, that a defect in the stones, which formed the upper division of the cornice, may have been supplied by having an ovolo fixed in this recess. In every specimen of pure Doric, the cornice has mutules. In examples to be found in Sicily, the drops from the soffit of the mutules, are cylinders of greater height than diameter; but in all the best examples, they are not more than half their diameter in height, and in some instances considerably less. In the temple of Theseus, the drops are frustums of cones; but, in the same specimens, those under the regula upon the epistyle have both a concave and convex flexure.

The hexastyle temple at Pæstum, instead of mutules, has the soffit formed into coffers; but, in this specimen, it is only the capital and triglyphs which bear any affinity to the Greek Doric; and even on the capital, in place of annulets, there is a row of delicate leaves crushed together between two astragals; and the triglyph being placed at the returning angle, they are over the centre of the columns; so that this specimen partakes more of the degenerate Roman than the pure Greek.

Having investigated what relates to the primary and secondary divisions of this order, and also noted the positions and relative proportions of the leading features, we shall add a farther statement respecting its columns, founded upon Table I. In this additional Table, the diameter at the base is considered the same in all, viz. unity. The whole numbers represent diameters. The figures to the right hand of the point are decimal parts of the diameter. The examples are arranged increasing in altitude.

Observations upon the Table.

From this Table it is evident, that the ancients did not scrupulously adhere to any precise proportions in their columns for different edifices; but not knowing the dates of the construction of the several specimens, we are unable to determine whether these differences existed at the same time, or succeeded each other in consequence of a change of taste. It may also be observed, that, of seventeen examples, the upper diameters of six are less than three-fourths, and eleven greater. The diminution of the superior diameter in the temple of Theseus is .772, which is something less than a mean between three-fourths and four-fifths: the half sum of these fractions being .775. This example of the temple of Theseus is one of the best of the Greek Doric, and may be taken as a rule; or in practice, to make the superior diameter three-fourths of the inferior, is still more simple, and sufficiently correct.

In every Greek Doric, the vertical face of the epistyle or architrave projects beyond the superior diameter, but is within the inferior one.

In the temple of Theseus, the height of the abacus is nearly one-fifth of the diameter, and the ovolo and annulets together are very nearly equal to the abacus. The height of the annulets is very nearly one-fifth of the ovolo. The horizontal dimension of the abacus extends, on each side, very nearly six times its height. The neck of the capital is nearly half the height of the annulets. In the temple of Corinth, and the Doric portico at Athens, the ovolo or echinus is of an elliptical shape; but in every other instance of Greek capitals, it is hyperbolical, excepting the single instance of the portico of Philip, king of Macedon.

Proportions established.

From the preceding dimensions and observations, we establish the following proportions for the construction of the Doric order: Considering the diameter that of a circle, at the lower end of a shaft the column is six diameters in height. The thickness of the upper end of the shaft is three-fourths of the lower, or it diminishes one-fourth of the diameter. The height of the capital is half a diameter. That of the ovolo, with the annulets, and that of the abacus, are each one-quarter of the upper diameter. The annulets are one-fifth of one of the parts. The horizontal dimension of each face of the abacus is six times its height. The entablature is divided into four equal parts; the upper one is the height of the cornice; the remaining are divided equally between the architrave and frieze. The inner edge of the angular triglyph is placed in a vertical line with the axis of the column. The height of the triglyph is divided into five equal parts; three of these parts give the distance of its returning face, and determine also that of the epistyle, and consequently include the breadth of the triglyph. The height of the capital of the triglyph is one-seventh of its whole height, and the capital of the metope one-ninth. The breadth of the triglyph is divided into nine equal parts, giving two to each glyph, one to each semi-glyph, and one to each of the three inter-glyphs. The metopes are square. The height of the cornice is divided into five equal parts; the lower is given to the fillet, the mutule, and drops; the next two to the corona; and the remaining two parts are subdivided and disposed amongst the several members, in the manner shewn in Plate CLVIII. The projection of the cornice is equal to its height; it is divided into four equal parts, giving three to the projection of the corona. The subdivisions in the Plate shew the profiles of the smaller members. In this example, the column is taken from the temple of Theseus, and the entablature from that of Minerva at Athens.

Plate CLVIII.

The number of annulets in the capital vary from three to five; and the number of horizontal grooves, which separate the shaft from the capital, vary from one to three.

In the application of the Doric order to temples, the shafts of the columns are generally placed upon three steps, which are not proportioned like these in a common stair, but to the magnitude of the edifice.

The preceding specimens have all been taken from Greek edifices, these being considered the only pure style of this fine order. The best example of Roman practice is that taken from the theatre of Marcellus, by Sir W. Chambers, to whose excellent work on civil architecture we refer our readers.

Ionic order.

Of the Ionic Order.

General remarks.

Although, in the Ionic, the primary division, into columns and entablature, and the secondary, of shaft, capital, architrave, frieze, and cornice, remained the same, yet the omission of some of the principal subdivisions of those parts, and the introduction of others entirely new, as well as the greater degree of delicacy in all, distinguishes this sufficiently from the Doric order, and establishes its claim as a distinct order or canon of Greek architecture. See Plate CLIX.

Plate CLIX.

The Ionian Greeks having become wealthy, and being, no doubt, influenced by the manners of their Asiatic neighbours, refined upon the simplicity of attic architecture, and invented a capital totally different from that employed in the mother country. Its origin is, however, problematical. Vitruvius reports it to have been made in representation of the curls in the head-dress of females; but other hints are quite as probable, as the spiral shape of the horns of rams, used in their sacrifices; or that assumed by the barks of some trees, when dried in the sun; or that of certain delicate vegetables, such as the slender fern, before it is quite unfolded; or the beautiful spiral forms of various sea-shells, any of which are sufficient to guide the fancy of an ingenious artist in composing the volutes of the capital of Ionia.

Origin of capital.

Architrave, frieze.

Cornice.

In the architrave and frieze, all appearances of triglyphs and guttæ are omitted; and in the cornice, instead of the bold mutules of the Doric, the ends of smaller pieces of wood, to which the covering tiles were fixed, are represented by what are termed dentils or teeth. This order also differed from the Doric, by having a base at the lower extremity of the shaft; the propriety of this might have arisen from the diameter of the shaft being much less than that of the Doric, in proportion to the height of the order, or the weight it had to sustain.

Base.

The rest of the Ionic order is not so precisely defined, or so uniformly adhered to, as similar parts in the Doric. The Temple of the Muses, on the Ilyssus, is composed of few, but very distinct and bold parts. The height of the volutes is three-fifths, and that of the whole capital two-thirds of the diameter of the shaft. If the entablature is divided into five parts, two are occupied by the architrave, which consists of a single facia, crowned with a cymatium; the remaining three are divided into five other parts, three of which are occupied by the plain part of the frieze, and the remaining two by the cornice. The cymatium of the frieze, which consists of a cima-reversa standing upon a bead, is worked out of the cornice. The cornice, as viewed in front, is composed of a corona, cymatium, and cima.

Temple of the Muses.

In the temple of Erectheus and Minerva Poliss at Athens, the architrave has three faciæ and a cymatium, and the cymatium of the frieze is worked chiefly out of the cornice. The height of the entablature, from the bottom of the lower facia of the architrave to the top of the cymatium upon the corona, if divided into nineteen parts, the architrave and frieze will each have eight, and the corona, larima, and cymatium will occupy the remaining three parts. In these specimens, the volutes have a singular degree of symmetry and beauty.

Minerva Polias.

In all the Greek Ionics, the height of the cornice, measured from the lower edge of the corona upwards, appears to have a constant ratio to the total height of the entablature, viz. nearly as 2 to 5, which seems the true one to accord with the character of the order. The great recess of the mouldings, under the corona, gives it a striking prominence, and prevents the cornice from appearing too heavy, though both the dentil band and cymatium of the frieze are introduced under it.

Cornice.

On account of the frieze being wanting in most of the Asiatic remains, although the architrave and cornice have been accurately measured, the height of the entablature cannot be ascertained. The only instance in which a frieze has been discovered is in the theatre of Laodicea; and there it is rather less than one-fifth of the entabla-

Frieze.

ture. In the temple of Bacchus at Teos, and Minerva Polias at Priene, the architraves are divided into three faciæ below the cymatium. Their proportions are very different from those at Athens, though also elegant in character and effect.

Cornice.

In all the Asiatic Ionics, the crowning mouldings of the cornices are cima-recta, less in projection than height. The dentil bands are never omitted, and their height is a mean between that of the cima-recta and of the larima, corona, or drip, being uniformly greater than that of the corona, and less than that of the cima-recta. The cymatium of the denticulated band is recessed upwards, being almost entirely wrought out of the soffit of the corona, which nearly conceals its height. The height of the cornice, from the top of the cima to the lower edge of the dentils, is equal, or nearly so, to that of the architrave. The height of the frieze, without its cymatium, may be about one-fourth of the whole entablature.

Column.

We have observed that the height of the Ionic column was originally eight diameters; the moderns have increased it to nine. The shaft is generally cut into 24 flutes, with as many fillets. The altitude of the entablature may, in general, be two diameters; but it may be increased, and should not be less than one-fourth of the height of the column in works of magnificence.

Base.

Temple on Ilyssus.

Attic base.

Temple of Bacchus at Teos.

The base of the Athenian Ionics consists of two tori, having a scotia or trochilus between them, separated from the tori, above and below, by two fillets; the fillet above the inferior torus projects, in general, as far as the extremity of the superior torus, and the fillet beneath the upper torus projects beyond both. The scotia is very flat, its section forming an elliptic curve, which joins the fillet on either side. The tori and scotia are nearly of equal altitudes. In the temple on the Ilyssus, there is a bead and fillet on the upper torus, joining the fillet to the scape of the column; in the same temple, as well as in that of Erectheus, the upper torus of the base is fluted; but the lower part, which joins the upper surface of the fillet above the scotia, is left entire. In the latter temple the lower torus of the base of the Antæ is receded; and in that of Minerva Polias it is fluted, each flute being separated from those on either side by two small cylindric mouldings of a quandrantal section, joining at their convexities. The upper scotia of the temple of Minerva Polias is also enriched with a guilloche. Vitruvius has, very properly, termed this the ATTIC BASE, it having been employed by the Athenians in all their Ionics; and, although the Ionians had another, more particularly appropriated to this order, they sometimes employed the Attic, as in the temple of Bacchus at Teos. In the temple of Minerva Polias at Priene, and that of Apollo Didymæus near Miletus, the bases consist of a large torus, three pair of astragals, and two scotiæ, inverted towards each other; the upper pair of astragals is below the torus, and the scotia intervenes between each pair. In the former of these temples, an additional astragal separates the torus from the shaft. The torus is elliptical with its under part fluted; there is likewise a flute in the upper part of the base. In the temple of Apollo Didymæus, the upper torus is semicircular, and each bead of every pair is separated by a narrow fillet. This base differs but little from that assigned to this order by Vitruvius, only in the former the scotiæ are inverted, and present a greater variety of profile.

Volute.

Minerva Polias.

Bacchus at Teos.

The volute, which is the great distinguishing feature of this order, in the Athenian Ionics, and the temple of Minerva Polias at Priene, the lower edge of the channel which runs between them is formed into a curve, bending downwards in the middle, and revolving about the spirals on either side. In the temple of Erectheus, and Minerva Polias at Athens, each volute has two channels formed by two distinct spiral borders; the borders forming the exterior volute, and the under side of the lower channel, have between them a deep recess or spiral groove, which diminishes gradually in breadth, till it loses itself in the centre of the eye. In the temple of Bacchus at Teos, the great theatre of Laodicea, and in all the Roman Ionics, the channel whereby the two volutes are connected has no border on the lower edge, but terminates with a horizontal line, falling in a tangent to the commencement of the second revolution of each volute.

In the temple of Erectheus, the column terminates with a fillet and astragal a little below the eye of the volute; and in the temple of Minerva Polias, it is terminated with a single fillet. In both instances, the colerino or neck is decorated with honey suckles. The upper annular moulding of the column is of a semicircular section with a guilloche.

Both Greek and Roman.

The capitals of both Greek and Roman Ionics have the eschinus, astragal, and fillet; the eschinus is always cut into eggs, surrounded with borders of angular sections with tongues between them; the astragal consists of a row of beads, having two small ones inserted between every two large ones. In all the Roman buildings, except the Coliseum, these mouldings are cut in the same manner.

Angular capitals.

Greek and Roman.

When Ionic columns stand in the flanks as well as the fronts of a building, two volutes at the corner of each angular column is contrived to present the same form in the flank as in the front, as in the temple of Bacchus at Teos, of Minerva at Priene, Erectheus, and that of the Muses at Athens, and likewise of Fortuna Virilis at Rome: the angular capitals have, in all these instances, one volute on each side, projected in a curve towards the angle. Amongst the ancient Romans, as at the temple of Concord at Rome, the capitals of all the columns are made to face the four sides of the abacus; and it was from this specimen that Scammozzi, encouraged by the example of Michael Angelo, composed the capital upon this principle, which bears his name.

Examples.

The following examples will shew the number of flutes and their form in the temples of the Ilyssus. Erectheus and Minerva Polias at Athens, Bacchus at Teos, Minerva Polias at Priene, and Apollo at Didymæus, near Miletus;—each column has 24 flutes, and as many fillets. The columns of the aqueduct of Adrian, the Ionic colonnade near the Lantern of Demosthenes, and the great theatre at Laodicea, also at the temple of Concord, the second order of the Coliseum, and the theatre of Marcellus at Rome, have their shafts plain; but the columns of the temple of Fortune, at the same place, have 24 flutes. The section of the flutes of the columns, in the temple on the Ilyssus at Athens, is elliptical; the flutes descend and follow the curve of the scape of the column in the following specimens, viz. the temple of Minerva Polias, and of Erectheus at Athens, the temple of Bacchus at Teos, and Minerva Polias at Priene.

Method of describing the Ionic Volute.

Rules to describe the Ionic volute.

PLATE CLXXXIV. Fig. 1.

To describe the Ionic volute with any number of revolutions or quarters to any given height, and to touch a circle of a given radius within the spiral.

Let AB, Plate CLXXXIV. Fig. 1. No. 1. be the height of the volute. Divide AB into two equal parts at C. From AB cut off AD, equal to the radius of the eye. Divide DC into as many equal parts as the volute is to consist of quadrants, (which, in this example, are 12,) at the points 1, 2, 3, &c. Draw CE, at any angle with AB, equal to two of these parts: draw 11 f perpendicular to CD, equal to CE: draw fg perpendicular to 11 f, equal to 11 Q: draw gh perpendicular to gf, equal to 10 P. Proceed in this manner until all the sides of the spiral fret are drawn. Produce 11 f to 1, fg to 2, gh to 3, and so on. Upon the centre at 11, with the distance d B, describe the arc B 1; from the centre f, with the distance f 1, describe the arc = 1, 2; from g, with the distance g 2, describe the arc 2, 3. Proceed in the same manner with all the remaining arcs, the last terminating at 12. Then, from the centre r, with the radius r 12, describe a circle for the eye of the volute; and the radius, r 12, of this circle will be equal to AD as required, provided the operation be accurately performed.

Plate CLXXXIV. Fig. 1. No. 2.

After the same manner may the inner spiral be drawn. Fig. 1. No. 2. shows the construction of the centres to a larger scale, and by a method not so liable to inaccuracy, as follows: Having made df equal to CE, divide it into halves at e; draw er perpendicular to df, equal to ed or ef, and draw $dinr$, and $fkor$. Make es, st, tr, equal each to G 2 on the scale: draw isk, nto parallel to df; make fg perpendicular to df, equal to 11 Q: draw the diagonal glp parallel to $dinr$: draw kl, op, nm, ih, perpendicular to df: draw gh parallel to 11 f: draw the diagonal hmq: draw lm and pq parallel to fd, and d, f, g, h, q, c, will be the centres. This method is not so liable to error, as taking the parts successively from the scale, and applying them to the spiral fret in the same order.

In order to show the truth of this universal method, we shall subjoin the following demonstration, which, it is hoped, will be satisfactory to the reader.

Let x represent any of the equal parts of which DC consists, and r the radius of the eye.

Then will $d\mathrm{B}=d\,1=\mathrm{CB}+x=$ the radius of the first quadrant, and $d\mathrm{A}=f\,1=\mathrm{CB}-x$ the radius of the second quadrant; therefore, $df=d\,1-f\,1=(\mathrm{CB}+x)-(\mathrm{CB}-x)=2x$, the first side of the fret; and CE will also be equal to twice x, as by the construction; likewise, let n be equal to the number of parts in CD; then will 1 F, the first parallel distance on the scale, be equal to $\frac{2x}{n}$; and the second $2\,\mathrm{G}=\frac{4x}{n}$; the third $3\,\mathrm{H}=\frac{6x}{n}$; but if the half sum of the extreme terms of this arithmetical progression be multiplied by their number, the product will be equal to the sum of the series. Now, the first term is $\frac{2x}{n}$, and the last term $=2x$; therefore, $\left(x+\frac{x}{n}\right)\times n=nx+x=\mathrm{DC}+x$, is the sum of the series; but $\mathrm{DC}+x$ is $=\mathrm{CA}+x-r=\mathrm{CB}+x-r$, equal to the length of the spiral fret. Now, let this last quantity be taken from $\mathrm{CB}+x$, the radius of the greatest quadrant, and there will remain r the radius of the eye as ought to be; for the difference of the radii of any two adjoining quadrants is equal to the side of the spiral fret between their centres, or, in other words, in the straight line passing through their centres, and the junction of their arcs.

Former methods imperfect.

The methods hitherto discovered for the description of volutes, are extremely imperfect and limited to three revolutions, and the eye to a certain portion of the height of the spiral. The method shown by Palladio, said, by Sir William Chambers, to be that of De l'Orme's, is imperfect, as the two adjoining arcs of any two revolutions cannot have the same tangent at their junction; and the straight line, which is a tangent to any two arcs, can only have one point of contact in the same revolution; but though this imperfection is remedied in Goldman's, yet, in the latter, the successive distances, on the lines of junction between two adjoining revolutions of the spiral, are very unequal, as the distances of the adjoining revolutions in the two upper quadrants are nearly equal, whereas, in the two lower quadrants, the distances between the adjoining revolutions of the same spiral decrease very unequally towards the centre; and this irregularity is extremely unpleasant to the eye.

But though the method we have shown is the most perfect and easy of any yet published, and has also the advantage of being universal in its application, it is far from being perfect, as it cannot be applied where the volute consists of many spirals, as in the Ionic order of the temple of Erectheus at Athens, and much less any of the other two which preceded it. There is one resource, however, by which this evil can be remedied, and by which perfection alone can be obtained, and this by the principles of the logarithmic spiral; for, in all other methods, the fillets and the intervals of the volute are never in continued geometrical proportion.

Though the principles of this curve has been long known, it is singular that its application to the Ionic volute has never been hinted at by any author, before the publication of the Principles of Architecture by Mr Peter Nicholson.

The following method of describing the Ionic volute, upon the principles of the logarithmic spiral, by means of a proportional compass, is not so liable to error, and is much more expeditious in practice, than a scale formed by the progression of the corresponding sides of a series of similar triangles, as shown in the second volume of that work.

Plate CLXXXIV. Fig. 2. No. 1.

Fig. 2. No. 1. To describe the Ionic volute similar to that in the temple of Erectheus, by the principles of the logarithmic spiral, the centre O, the cathetus OA, and the distance AI, between the first and second revolutions of the outer spiral, being given.

To describe the volute.

Produce AO to E, and draw GOC at right angles to AOE; bisect the angles AOC and COE by the right lines BOF and DOH, and the angles EOG and GOA will also be bisected. Find a mean proportional between OA and OI, and make OE equal to it; find also a mean proportional between OA and OE, and make OC equal to this mean; likewise find a mean proportional between OA and OC, and make OB equal to this last mean. Set the proportional compass, so that the distances between the two pair of points will have the same ratio to each other, as OA to OB; then opening the distance between the widest pair of points from O to A, and turning the compass to the narrowest pair; make OB equal to that distance. Again, taking OB with the widest end, make OC equal to the distance of the narrowest end. Proceed in this manner, by alternately taking the length of the last radius found between the widest points, and applying the distance between the narrowest points from the centre upon the succeeding line as a radius, until the last radius approach the eye, then through all the points draw a curve, which will be one of the spirals. In the same manner, and at the same setting of the compass, each of the inner spirals are to be drawn as the spiral *abcdefghi*.

Another method. Fig. 2. No. 2.

Another method of doing this, without marking the drawing, is to make a scale AB, with the proportional compass in the same manner as marking the distances from the centre, viz. having set the proportional com-

Fig. 2.
No. 2.

pass as before, make OA, No. 2, equal to OA, No. 1; and make Ob equal to the distance of the shorter ends. Take Ob with the longer ends, and mark the distance Oc with the shorter ends. Again, take Oc with the longer ends, and mark Od with the shorter ends. Proceed in this manner through the whole eight points, which are the number in a revolution. Draw OB of any length, making any angle with OA; draw AB, bB, cB, dB, &c. Take the successive distances OA, Ob, Oc, Od, &c. upon the edge of an ivory rule or straight slip of paper, and apply them in No. 1. from O to A, from O to B, from O to C, &c. to I, marking the points A, B, C, D, &c. In No. 2, draw iE parallel to OB, cutting AB at E; draw EF parallel to AO, cutting iB at G; draw GH parallel to OB, cutting OB at H; and draw HI parallel to AO. Then EF will be a scale to set off the second revolution in the same manner as the first; and in like manner HI will be a scale for the third revolution. By this means, and from the same scale, the whole number of intermediate spirals may be drawn without pricking the paper, marking the points with a sharp pencil instead of a steel point.

Proportional spiral.
PLATE CLXXXIV.
Fig. 3.

To describe the proportional spiral with a compass, the same data being given as before, Fig. 3.

Let the point C be ascertained as before. Join ABC, which bisect by a perpendicular BD; make BD equal to BA or BC; draw DA and DHC, and the diagonal DOF; at right angles thereto draw HOJ. Draw HFE parallel to AD, FJG parallel to DHC; proceed towards the centre with every succeeding point in the same manner; and D, H, F, J, &c. will be the centres. From D, with the distance DA, describe the quadrantal arc AC; from H, with the distance HC, describe the quadrantal arc CE; from H, with the distance HE, describe the quadrantal arc EG; proceed in this manner until as many quadrants are described as that the last will meet the eye of the volute, and this will complete one of the spirals. Suppose again it were required to draw another of the interior spirals through the point M in the cathetus OA; draw MN parallel to AC, cutting OC at N, then N will be the next point in the quadrant; proceed to find all the succeeding quadrants of this spiral as before, and thus the volute may be completed.

General proportions of the Ionic order.
PLATE CLIX.
Fig. 1.

The general proportions of the Ionic order for practice, is as follows. Fig. 1. Divide the whole height into twenty-one equal parts; give four to the height of the entablature. Divide the height of the entablature, Fig. 2. into three equal parts; make the cornice, frieze, and architrave, each one part: divide the height of the architrave into four equal parts; give one to the mouldings of the upper part or capital: divide the capital of the architrave into nine equal parts; give one to the upper fillet, three to the cavetto, four to the ovolo, and one to the bead: divide the height of the frieze into six equal parts; and give the upper one to its capital: divide the height of the cornice into three equal parts; divide the upper part into six parts, give one to the upper fillet, four to the cima-recta, and one to the lower fillet, and turn one downwards for the ovolo under; divide the lower third of the cornice into six equal parts, and dispose of the parts as appears by the scale. The height of the base, including the plinth, is half the diameter; the parts are proportioned in height as appears by the scale. The whole height of the capital is three-fourths of the upper diameter; the height of the volute 7-12ths of the lower diameter. Dividing the height of the volute into three equal parts; the top of the lower one reaches to the bottom of the ovolo the second division upon the top of the festoon: the smaller members will be found by subdivision. The juttings of the members are as follows: the cornice projects equal to its height; the projections of the intermediate members will appear sufficiently clear by the horizontal scales affixed to the Plate. The general projection of the base is one-sixth of the lower diameter of the column.

The entablature is principally imitated from the elegant example of the temple of Minerva Polias at Priene, and the capital from the Ionic temple on the Ilyssus at Athens, which is one of the boldest examples, and marks the character of the order in the most decided manner.

Of the Corinthian Order.

Corinthian order.

Introduced by Scopas.

Unless we admit the account given by Vitruvius respecting the invention of the capital by Callimachus, who is said to have been an Athenian sculptor, and a contemporary of Phidias about 540 B. C. there is no certain evidence with regard to the time when this order was established. Pausanias (book viii.) says, that in the fourth century before the Christian æra, it was introduced by Scopas in the upper range of columns in the ancient temple of Minerva at Tegea; but it has been alledged, that there is a strong probability that this temple was only begun by Scopas, but being left unfinished, had this upper range added, upon the lower ancient Doric, under Roman influence. There must certainly have been some particular reason why this order was called Corinthian; but Doric remains only have been discovered on the site of that city by modern visitors.

Has an attic base.

In all the examples in Stuart's *Athens*, this order has an attic base; the upper fillet of the trochilus or scotia projects as far as the upper torus. In the monument of Lysicrates, the upper fillet of the base projects farther than the upper torus, which is an inverted ovolo.

Shaft compared with Ionic.

Vitruvius observes, that the shaft has the same proportions as the Ionic, except the difference which arose from the greater height of the capital, it being a whole diameter, whereas the Ionic is only two-thirds of it. But this column, including the base and capital, has, by the moderns, been increased to ten diameters in height. If the entablature is enriched, the shaft should be fluted. The number of flutes and fillets are generally 24; and frequently the lower one-third of the height has cables or reeds, husks, spirally twisted ribbands, or some sort of flowers inserted on them.

Capital.
PLATE CLX.

Description.

The great distinguishing feature of this order is its capital, (see Plate CLX.) which has for two thousand years been acknowledged the greatest ornament of this school of architecture. The height is one diameter of the column, to which the moderns have added one-sixth more. The body, or nucleus, is in the shape of a bell, basket, or vase, crowned with a quadrilateral abacus, with concave sides, each diagonal of which is equal to two diameters of the column. The lower part of the capital consists of two rows of leaves, eight in each row; one of the upper leaves fronting each side of the abacus. The height of each row is one-seventh, and that of the abacus one-eighth of the whole height of the capital. The space which remains between the upper leaves and the abacus is occupied by little stalks, or slender caulicolæ, which spring from between every two leaves in the upper row, and proceed to the corners, and also to the middle of the abacus, where they are formed into delicate volutes. The sides of the abacus are moulded, as in the Stoa, or portico, and arch of Adrian at Athens, and also the ruin at Salonica: the curves of the sides are continued until they meet in a sharp horn or point. In the attic capital, the small divisions of the leaves were pointed in imitation of the acanthus. In Italy they most generally resembled the olive.

Best specimens.

The best specimens are the monument of Lysicrates, the Stoa, and arch of Adrian at Athens; and the pantheon of Agrippa, and the three columns of the Campo Vaccino at Rome. In the monument of Lysicrates, the lower part of the capital consists of two rows of leaves; the lower row is plain, and the upper one raffled; and the latter is nearly twice the height of the former. The number of leaves in the upper row is eight, in the lower, sixteen. In the upper row, the sides of the middle leaf, upon each front of the capital, is covered by the flank leaves; and the whole of the leaves appear as if fastened to the body, or bell part, by a rose-headed pin, on each side of the flank leaves. Each of the helices, or stalks, proceeds from the sides of the middle leaf at the top of each row, as if they sprung from one common vertical stalk; then rising upwards, they take a direction towards the left, in a line of contrary curvature, and terminating in foliage. The volutes in the middle of the capital are quadruple, each one of each pair of one side, meeting each one of the other pair upon that side. And as each pair of volutes spring from the same trunk, and begin at the same horizontal position of the curve, each one of each pair is turned outward, and varies in size, the lesser being above, and the greater below. The four volutes form a curvilinear quadrilateral figure, by having their convex sides presented to each other. The upper or lesser pair support the honeysuckle which covers the middle part of the abacus. The corners of the abacus are cut off; and the hollow or lower member forms an inverted scotia, which is nearly four times the height of the crowning ovolo.

It may be observed generally, in the Greek Corinthian, that the volutes terminate in a point in the natural spiral, without either coiling round a circular eye, or bending backwards in a serpentine form, as in most of the Roman specimens.

This order seems never to have been much employed in Greece before the time of the Roman conquest; but this powerful people employed it almost exclusively in every part of their extensive empire; and it is accordingly in edifices constructed under their influence that the most perfect specimens are found.

We have already noticed the remark of Vitruvius, that Corinthian columns were sometimes surmounted by a Doric entablature, which, besides that it is in itself very extraordinary, is not supported by any antique example now to be found. His observation respecting the Ionic entablature over the same kind of columns is verified in a number of instances.

Arch of Adrian.

The arch of Adrian at Athens, has a cornice with dentils, a plain frieze, an architrave with two plain faciæ, and an attic base.

Temple at Jackly.

A temple at Jackly, near Mylassa, has a cornice with dentils, a swelled frieze, an architrave with three plain faciæ, and an attic base.

Salonica.

At Salonica, (the ancient Thessalonica,) a building called the Incantada, has a cornice with dentils, a swelled frieze ornamented with flutings, an architrave with three plain faciæ, and an attic base.

Vesta.

The temple of Vesta, or Tivoli, has a plain cornice, with a dentil band uncut, an ornamented frieze, an architrave with two plain faciæ, and an attic base.

Antoninus and Faustina.

At Rome, the temple of Antoninus and Faustina has a plain cornice, with the dentil band uncut, an ornamented frieze, an architrave with two faciæ divided by an astragal, and an attic base.

Portico of Septimius Severus.

The portico of Septimius Severus, in the same city, has a plain cornice, with a small uncut dentil band, a plain frieze, and an architrave with three faciæ divided by mouldings.

In all these instances, the entablature and base are similar to those generally observed in the Ionic order, from which these Corinthian examples differ only in the form of their capitals. But in those which we are now about to cite, it will appear, that the Romans attempted to give the Corinthian order a more distinct character, by appropriating to it a peculiar entablature and base, and thus making a complete order of what might be previously regarded as a composition, in which light Vitruvius seems to have considered it.

Pantheon.

The portico of the pantheon has a cornice with modillions, and an uncut dentil band, a plain frieze, an architrave with two faciæ divided by mouldings, and a Corinthian base.

Temple of Peace.

The Temple of Peace, at Rome, has a cornice with modillions and dentils, a plain frieze, and an architrave with three faciæ divided by mouldings.

Campo Vaccino.

In the Campo Vaccino, the three columns supposed by some to have belonged to a temple of Jupiter Stator, and by others to a temple dedicated to Julius Cæsar, have a cornice with modillions and dentils, a flat frieze, an architrave with three faciæ divided by mouldings, and a Corinthian base.

Jupiter Tonans.

The temple of Jupiter Tonans, at Rome, has a cornice with modillions and dentils, a flat frieze, and an architrave with three faciæ divided by mouldings.

Constantine's arch.

The arch of Constantine has a cornice with modillions and dentils, a plain frieze, an architrave with three plain faciæ, and an attic base.

Temple at Ephesus.

At Ephesus, the temple supposed by Chandler to have been erected by permission of Augustus, in honour of his uncle Julius, has a cornice with modillions and dentils, a swelled and ornamented frieze, an architrave with three faciæ divided by mouldings, and an attic base.

Nismes.

The Maison Quarré, at Nismes, has a cornice with modillions and dentils, a flat frieze, an architrave with three faciæ divided by mouldings, and an attic base.

To these we may add the following, in which the alteration seems but partially to have taken place; there being neither dentils nor dentil bands in the cornices, and the mutules, from their situation, appearing rather like a variation from the proper Ionic dentil, than a new member.

Portico at Athens.

A portico at Athens, supposed by Mr Stuart to be the ancient Pœcilè: a cornice with mutules of two square faces, an architrave with two plain faciæ, and an Attic base.

Frontispiece of Nero.

The frontispiece of Nero, at Rome: a cornice with mutules of two square faces, an ornamented frieze, and an architrave with two faciæ, divided by an ogee.

Moderns.

Palladio.

Of the modern architects who have treated of this order, Palladio makes the column 9½ diameters high, one-fifth of which he gives to the entablature, consisting of a cornice with modillions and dentils, a flat frieze, and an architrave with three faciæ, divided by astragals; the base is attic.

Scammozzi.

The design of Scammozzi bears a general resemblance to that of Palladio, but his column has ten diameters in its altitude; his entablature is one-fifth of this height; the cornice has modillions, the architrave consists of three faciæ, divided by astragals, and the base is attic.

Serlio.

Serlio, following Vitruvius, has given this order an Ionic entablature, with dentils, and the same proportion of the capital; his column is nine diameters high, and has a Corinthian base.

Vignola.

Vignola's Corinthian is a grand and beautiful composition, chiefly imitative of the

Practice.

three columns. He makes the column ten diameters and a half in height; the entablature is a fourth of that altitude, the cornice has modillions and dentils, the frieze is plain, the architrave of three faciæ divided by mouldings, and the base is attic.

Sir William Chambers.

Sir William Chambers has observed, that "the Corinthian order is proper for all buildings where elegance, gaiety, and magnificence are required. The ancients employed it in temples dedicated to Venus, Flora, Proserpine, and the nymphs of fountains; because the flowers, foliage, and volutes, with which it is adorned, seemed well adapted to the delicacy and elegance of such deities." This theory, however plausible, is unsupported, or rather contradicted, by facts.

General observations.

The Romans, who appear, as already hinted, to have adopted the Corinthian order in preference to the others, employed it indiscriminately, and erected Corinthian temples to Jupiter, Mars, and Neptune, to whom the Greeks dedicated temples of the Doric order. The temples of Minerva at Athens and at Sunium are Doric; that of Minerva-Polias, at Priene, is Ionic. The temple of Jupiter Olympus at Elis was Doric; that at Athens, built by Adrian, is Corinthian. The numerous temples of the Grecian colonists in Sicily and Italy, are uniformly Doric, marked by the most severe and massive simplicity. The cities of Ionia present the best examples of a chaste and elegant Ionic: and the magnificent structures of Balbec and Palmyra are wholly of the Corinthian order, and in the most florid style of ornament. Whence we may conclude, that the choice of the orders of architecture was rather governed by national taste, than by any ideas of identity between the character of the style, and that of the object to whom the building was to be devoted.

In the following Table will be found the proportions of some of the principal examples of the Corinthian order; in examining which, it is to be recollected, that the several members are measured by the lower diameter of the shafts, which is divided into 60 parts.

Proportion of capital.
PLATE CLXXXV.
Fig. 1.
No. 1.

Projection of the Corinthian capital. (See Plate CLXXXV. Fig. 1.) No 1. the plan, No 2. the elevation. No 1. the semi-plan, is divided into eight equal parts, which, being carried up perpendicularly to the elevation, gives the centres of the leaves of which the projections are formed by those upon the plan. The length of the diagonal of the abacus is two diameters; the centre of each side is determined by the vertex of an equilateral triangle. The elevation shews the general outlines of the leaves before the foliage is cut.

No. 2.

No 2. shews the general form and manner of raffling the leaves.

No. 3.

No 3. shews the front of the leaf according to the three columns in the Campo Vaccino.

No. 4.

No 4. is a modillion. No 1. being the side, and No 2. the profile.

Modillion.
PLATE CLX.

Practical example: (Plate CLX.) Referring to the manner of explanation of the Doric and Ionic, the ratio of the parts of the Corinthian will be sufficiently evident, from consulting the before mentioned Plate. This example is imitated chiefly from the Pantheon of Agrippa at Rome, it being a chaste and elegant specimen. Others, still richer, may be seen in the works of Sir W. Chambers, and Mr P. Nicholson.

Roman Orders.

Roman orders.
General observations.

Besides the three Greek orders, two others were introduced in ancient Italy, viz. the *Tuscan* and *Composite.* In their general character they are governed by the canons of the Greek school, and have indeed very little claim to be separately classed: Our notice of them will therefore be proportionally confined.

Tuscan.

The title of the first leads us to assign its origin to Tuscany, and this conjecture is strengthened by that people being admitted as the offspring of Dorians. No ancient remains of this order having been discovered with entablatures, it is only from the accounts given by Vitruvius, that the form and ratio of its members can be determined; he allows seven diameters for the height of the columns, and diminishes the upper part one fourth half of the diameter; the base is half a diameter in height, one of which is given to a circular plinth, and the other to a torus; the capital is also half a diameter in height, and one in breadth upon the abacus; the height is divided into three parts, one of which is given to the abacus, one to the echinus, and the third to the hypotrachelian and apophygis; the architrave has two faces, with an aperture between them of about $1\frac{1}{2}$ inch for the admission of air to preserve the beams; the lower face is vertical upon the edge of the top of the column; the frieze is plain and flat; the mutules of the cornice project over the beams and walls, equal to one fourth of the height of the column.

The columns of Trajan and Antonine are specimens of the Tuscan, though being eight diameters high, they exceed, by one diameter, what is generally assigned to this order. St Paul's church, Covent Garden, in London, is the best modern example.

Composite.

In the *Composite order* the upper part of the capital is that sort of Ionic which presents a similar face on each of the four sides. The lower part consists of two rows of acanthus leaves, as in the Attic Corinthian. The column of the Roman edifices, with composite capitals, have, in general, Corinthian entablatures; the arches of Septimius Severus, and the Goldsmiths at Rome, have Ionic entablatures.

Modern architects have generally adopted the entablature of the frontispiece of Nero, or introduced adventitious members of other orders, as the denticulated band of the Ionic with its cymatium, between the modillions and cymatium of the frieze of the Corinthian. The modillions employed in the composite order differ from those of the Corinthian in being more massive, composed of two faces, and having a cymatium like an architrave. Indeed the capital being much bolder than the Corinthian, all the other members should be made of suitable magnitude.

The Romans employed this order chiefly in triumphal arches. The moderns have introduced it in various sort of works of the greatest magnificence.

Of Persians, Cariatides, and Termini.

Cariatides.

Besides columns, the Greeks sometimes supported their entablatures by human figures; when these represented males, they were named Persians, out of contempt for their nation; when the form was of females, they were called Cariatides, as a mark of disgrace to the inhabitants of Caria for having aided the Persians in one of their wars with the Greeks. Whether the Greeks invented this mode, or copied it from the edifices of Upper Egypt, or the temples or tombs of India or Persia, it is not necessary here to inquire. In Stuart's *Athens* there is a fine specimen of Cariatic figures supporting an entablature consisting of an architrave cornice. Various fragments of male figures are also met with amongst Roman antiquities, whose attitudes and acompaniments are evidence of their having been employed for similar purposes. Although, in the bitterness of contest, there may have been a satisfaction in thus employing the figures of their enemies, yet these associations being local and temporary, it is improper to degrade the human form into lasting expressions of slavery, or merely to perform the offices of blocks of wood or stone.

Greeks.
Egyptians.
India.

Termini.

The termini derive their origin from stones employed to mark the boundaries of property. To render these inviolable, Numa Pompilius consecrated them, and built a temple to Terminus on the Tarpeian rock. This deity was at first represented only by a large stone, but in process of time the top of it was cut into the form of a human head and shoulders, and the lower part into the shape of a sheath or inverted frustrum of a square pyramid, which has continued to be the general form, except that sometimes feet are added.

They have been employed as ornaments in gardens, and also at the side of chimney-pieces. They appear subject to similar objections as the Persians and Cariatic figures. To squeeze a man into a sheath, to be constantly exposed to the inclemencies of the weather in gardens, or wasted by a fire while supporting the entablature of a chimney, is, to say the least of it, a blameable conceit.

Colonnade.

Colonnade, a range of attached or insulated columns, supporting an entablature, is named according to the number of columns which support the entablature or fastigium; *tetrastyle*, when there are four; *hexastyle*, when six; *octostyle*, when eight; and *decastyle*, when ten.

The intervals between the columns, measured by their inferior diameter, is called *the intercolumniation*, whence the area between every two columns is termed *an intercolumn*.

Intercolumn.

The intercolumniation is of five denominations, viz. *the aræostyle*, or thinly set, when the columns are at the distance of four diameters; *the diastyle*, when they are at three diameters; *the eustyle*, when at two and a quarter; *the systyle*, when at two; and *the pycnostyle*, or thickly set, when at the distance of one diameter and a half. Of these the eustyle was in most general request among the ancients; and though, in modern buildings, both the eustyle and diastyle are employed, the former has obtained a marked preference. The pycnostyle is frequently rejected from want of room; and the aræostyle is not considered to yield sufficient support to the entablature, and is only applied to rustic structures of Tuscan intercolumniation, where the columns are lintelled with wooden architraves. See Plate CLXXXVI.

Plate CLXXXVI.

The intercolumniations of the Doric order are regulated by the number of triglyphs, one of which is placed over every intermediate column. When there is one triglyph over the interval, it is called *monotriglyph*; when there are two, it is called *ditriglyph*, and so on, according to the progression of the Greek numerals. The intercolumniation of the Grecian Doric is rarely any other than the monotriglyph, there being but two deviations from it at Athens, in the Doric portico, and in the prophylæa; and even in these instances, the exception applies only to the middle intercolumniations, which are ditriglyph, and were necessary from their situation, being opposite to the principal entrances. Indeed, from the massive and bold character of the Grecian Doric, the monotriglyphic succeeded best; but in the Roman Doric it would not be convenient, because the passage between the columns would be too narrow, especially in small buildings; and therefore the ditriglyphic is to be preferred.

When the solid parts of the masonry of a range of arcades are decorated with the orders, the intercolumns necessarily become wide, and the intercolumniation is regulated by the breadth of the arcades and of the piers. Vignola uses the same intercolumniation in all his orders; and though this practice is condemned by some, it is founded upon a right principle, as it preserves a constant ratio between the columns and the intervals.

Coupled columns.

Coupled, grouped, or clustered columns, seem not to have been used by the ancients. In the temple of Bacchus, at Rome, indeed, we find columns standing in some sort in pairs; but it must be observed, that each pair is only placed in the thickness of the wall, and not in the front; wherefore, they may be called two rows of distinct columns, one almost immediately behind the other, rather than a coupled row. In the baths of Diocletian, and in the temple of Peace at Rome, we find groined ceilings sustained by single Corinthian columns, which at once present a meagre appearance, and furnish but an inadequate support.

The moderns seldom employ more than one row of columns in either external or internal colonnades; for in double rows, the back range destroys the perspective regularity of that of the front; and the rays of light, proceeding from both ranges, produce confusion. Pilasters placed behind a row of insulated columns are liable to the same objection, except that the relief is stronger, owing to the rotundity of the one being contrasted with the flat surface of the other.

In buildings upon a small scale, as temples and other ornamental erections in gardens, the intercolumniations, or at least the central one, must be broader than the positive dimensions of the pillars would admit.

Antæ.

Antæ.—Though the earlier architects of Greece were either unacquainted with the use of pilasters, or refused to introduce them in their designs, they frequently placed a kind of square pillars at the ends of their walls, which they called *antæ,* and which sometimes projected to a considerable distance from the principal front, forming the pronaos, or vestibulum. The breadth of these antæ was always much less on the flanks of temples, than on the front; and sometimes they had columns between them, in which case, the return within the pronaos was of equal breadth with the front. The capitals of the antæ never correspond with those of the columns, though they always retain some characteristic marks, by which the order may be distinguished.

Pilasters.

Pilasters are rectangular prismatic projections, advancing from the surface of the wall, furnished with bases and capitals similar to those of the columns whose entablatures they assist in supporting. They differ from columns, in having their horizontal sections of a rectangular figure, whilst the sections of columns are either complete circles, or sections of circles, equal to, or greater than semicircles. They are probably of Roman origin; there being but few Grecian buildings, and those of the latter ages, (except the monument of Thrasyllus,) in which they are repeated at regular intervals, as in the monument of Philopapus; but of their application in Roman works we have numberless instances. Vitruvius calls them *parastatæ.*

When ranged with columns under the same entablature, or behind a row of columns, they have, as we have already observed, their bases and capitals like those of the columns, with the corresponding parts at the same heights: when placed at the angles of buildings, the breadth of the return is equal to that of the front. The trunks, also, have frequently the same diminution as the shafts of columns, as in the arches of Septimius Severus and of Constantine, the frontispiece of Nero, and the temple of Mars Ultor, at Rome. In these cases the top of the trunk is equal to the soffit of the architrave, the upright face of which rests on the capital, in the same perpendicular with the top of the pilaster. When the pilaster is undiminished, and of the same breadth as the bottoms of the columns, the face of the architrave resting on the capital, retreats within the head of the trunk, as in the pantheon of Agrippa.

Pilasters may be either plain or fluted, without regard to the columns. Thus, in the portico of the pantheon, the columns are plain, and the pilasters fluted; but in that of Septimius Severus, the former are fluted and the latter plain, the architects seeming to be governed by no other rule than their taste. The angles, or coins, of fluted pilasters are frequently strengthened with a bead, as in the pantheon, and the flutes are generally of a semicircular section. Sometimes the faces of pilasters are sunk within a margin, and the pannels charged with foliage, arabesque or grotesque ornaments, instruments of music or war, or of all these compounded. In the arch of the Goldsmiths, at Rome, the pannels are decorated with winding foliage and trophies of war.

Pilasters.

When placed on the front or outside of a building, pilasters should project one-fourth of their breadth at the bottom; but in the interior, or behind a row of columns, they should not project more than one-eighth of that breadth.

In a large recess, when an entablature is supported by an even number of insulated columns, with each end terminating and resting on a wall or pier, a pilaster is very commonly placed against each wall or pier, to support the extremities of the architrave. When the entablature over the columns is recessed within the surface of the wall or pier, the pilaster projects towards the column, shewing its thickness on the front, with its breadth facing the void or adjacent column. In this case, the architrave may either profile against the sides of the aperture or recess, or it may return at each interior angle; and again at the exterior angles, proceeding along each wall or pier.

When the intermediate columns and extreme pilasters are so ranged, as to project a small distance beyond the face of the wall at each end, the pilasters shew the same breadth towards the front as towards the void, that the entablature may remain unbroken, as in the chapels of the pantheon; but if breaks be unavoidable, they must be at the extremities, or most distant angles.

Pilasters are not only ornamental to a building, but they also tend to strengthen it greatly; to which we may add, that they become an object of economy, as being less expensive than columns. In situations where they are either placed behind a range of columns, or for the support of the extremes of an entablature across an opening, they are also more concordant with the walls to which they are attached.

Clustered pilasters.

Clustered pilasters, or those which have both exterior and interior angles, with their planes parallel and perpendicular to the front, may be executed with good effect, when the order is plain, as in the Tuscan; but in the Doric, Ionian, Corinthian, and Roman orders, where triglyphs and capitals meet but imperfectly in the interior angles, such a junction should be avoided as much as possible. The same may be observed of Ionic and Corinthian capitals of half pilasters meeting each other in the interior angles of rooms. In the Ionic order, a difference must be made between the capitals of pilasters and of columns; for, in the latter, the projection of the ovolo is greater than that of the volutes; but, the horizontal section of the ovolo being circular, the ovolo is bent behind the hem or border of the volutes; therefore, if a vertical section be conceived to pass through the axis of the column, perpendicular to the face, and another through the middle of the breadth of the pilaster, the corresponding mouldings being equal in both sections; then, because the horizontal section through the ovolo is rectangular, as in the trunk, the ovolo would, if continued, pass over the volutes, or by terminating abruptly, shew the profile of the moulding, which is a palpable defect. It therefore becomes necessary, either to give the ovolo but a small projection, or to make it so prominent in the front, that its extremities may appear to retire behind the border of the volutes; otherwise, the volutes must be twisted from their original plain surface, so that every part of the spirals may be projected towards the eye; or the whole abacus, with the volutes, must be protruded beyond the projection of the ovolo. The same inconvenience will occur in the instances of the Corinthian and composite capitals, in which the upper part of the vase projects beyond the middle of the abacus, and would pass over the faces of the spirals or volutes of the capitals of the pilasters.

Orders upon orders.

Orders upon orders.—In placing one order above another, we shall be naturally led, by the known laws of gravity, to give the strongest and heaviest the lower place, and the weakest and lightest the upper. Symmetry and strength will also direct us to keep all their axis in the same vertical line.

In columns of equal diameters, the altitudes increase from the Tuscan, by the gradations of the Doric and Ionic to the Corinthian. In this progression, we perceive that the Tuscan is stronger than the Doric, the Doric than the Ionic, and the Ionic than the Corinthian; consequently, if the Doric be the lowest order, the succeeding one must be the Ionic; if a third be added, it must be the Corinthian.

Vitruvius, book v. chap. vii. directs the height of the columns of the superior order, to be a fourth less than those of the inferior; but Scammozzi's rule, which is esteemed the best, is, that the lower diameter of the superior column should be equal to the upper diameter of the inferior, so that the different shafts bear the appearance of one long tapering tree cut into so many pieces; a disposition appropriately corresponding to the origin of columns.

According to the rule of Vitruvius, if an Ionic column of nine diameters were to be raised upon a Roman Doric of eight, the lower diameter of the Ionic would be two-thirds of that of the Doric, which is a much less quantity than is to be found in any ancient or modern example of the diminution of the Doric shaft.

In insulated columns, when the diminution of the superior order is very considerable, the intercolumn becomes so wide, and the entablature so small and weak, as to be in danger of breaking, which defect must be still increased, if a third range be added: whence we may again infer, that the theory of Scammozzi is preferable to that of Vitruvius.

Example.

For the sake of example, we shall suppose the stronger order to be made the superior, as the Doric on the Ionic. Here let the shaft of the Doric diminish five-sixths of its lower diameter, and its height will be but six diameters and two-thirds of the Ionic below, which would make a complete attic of the Doric, and render the application of the orders in this inverted manner useless, as they could not be made to accommodate the stories of the building, neither would the upper ranges support their own entablature.

When the front of a building is to have two or more orders in the altitude, the succession must be complete, or the symmetry will be destroyed by the abrupt contrast of the parts. In attached columns, the superior order may be permitted to recede, without danger either of greatly offending the eye, or of impairing the strength of the structure, as may be seen in the theatre of Marcellus. (See Plate CLXXXVI.) But when the stories of orders are insulated, the axis of the superior and inferior columns must be kept in the same vertical lines.

Theatre of Marcellus. Plate CLXXXVI.

In cases where the upper order only consists in the centre of that below, in two equidistant parts from the middle, the portions of the entablature of the lower order, in which there is no superior order, are generally finished with a balustrade, level with the sills of the windows.

We have but few examples in England, of more than two ranges of columns in the same front. Indeed, when there are three, it is difficult to preserve the character of each, without some striking inconsistencies and defects in the intercolumniations.

The first and second orders should stand on plinths, as likewise the third, when there is one; the point of view regulating those of the upper stories. In this case, pedestals should be omitted in the upper orders; but if there be one, or a balustrade under the windows, the base and cornice should have but a small projection, and be continued to profile upon the sides of the columns.

When stories of arcades are raised one upon another, and the piers decorated with orders, the inferior columns should stand on plinths, and those of the upper stories on pedestals, that the arches may receive a due proportion.

In some cases, instead of employing several orders one above another, the ground floor of a building is made in the form of a basement, on which is placed the order by which the principal story is decorated.

Plate CLXXXVI.

In Plate CLXXXVI. examples will be found of orders upon orders, with and without arcades and pedestals. They are taken from the inside of the temple of Paestum,—the outside of the Coliseum,—the theatre of Marcellus at Rome, and Whitehall in London.

Arcades.

Arcades.—When an aperture in a wall is too wide to be lintelled, it is arched over, and receives the appellation of *an arcade*, which term, in the plural number, indicates a continued range of such apertures. They are not so magnificent as colonnades, but are stronger, more solid, and less expensive.

In the construction of arcades, the piers require the utmost care, to have them of sufficient strength to resist the pressure of the arches, particularly those at the extremities. In large arches, the key-stones should never be omitted, and they should be carried to the soffit of the architrave, where they will be useful in supporting the centre of the entablature, which would otherwise have too great a bearing. The altitude of arcades should never be much more nor much less than double their breadth. The breadth of the pier should seldom exceed two-thirds, nor be less than one-third of that of the arcade; and the angular one should have the addition of a third, or even one half more than the rest, according to the nature of the design. The impost should not be less than a ninth, nor more than a seventh of the breadth of the arch; and the archivolt not less than a tenth, nor more than an eighth of the same breadth. The bottom of the key-stone should be equal in breadth to that of the archivolt; and its length not less than one and a half, nor more than double its bottom breadth. In groined porticos, the thickness of the piers depend on the width of the portico and the superincumbent buildings. It should not, however, where beauty and symmetry are consulted, exceed one-third, nor be less than one-fourth of the breadth of the arcade.

When the arcades form blank recesses, with the backs pierced for doors, or windows, or recessed with niches, the recesses should be at least sufficiently deep, to keep the most prominent parts of the dressings entirely within their surface.

The decorations of arcades may consist of rustics, columns, pilasters, cariatides, persians, or termini, surmounted with appropriate entablatures; and when the piers are of sufficient breadth, niches are introduced. The arch is either surrounded with rustic work, or with an archivolt, sometimes interrupted at the summit with a key-stone, in the form of a console, or marsh, or some other appropriate sculpture. In some instances, the archivolt rises from a platband, or impost, placed on the top of the piers; in others, from an entablature, supported by columns on either side of the arch. Sometimes the arches are entirely supported by single or coupled columns, without the entablature, as in the temple of

Temple of Faunus.

Faunus at Rome; but this is departing from the purest Roman style, and approaching to the Gothic.

Arches of Septimius Severus and Constantine.

Amphitheatres.

In cases where the columns are detached, as in the arches of Septimius Severus, and of Constantine, it becomes necessary to break the entablature, and to make its projection over the intercolumns, the same that it would have been had pilasters been used, or just sufficient to relieve it from the surface of the wall. Though this be requisite in all intercolumniations of great width, it should be practised as little as possible, because it destroys simplicity and the genuine use of the entablature. In the upper stories of the theatres and amphitheatres of the Romans, the arcades stood upon the podia, or interpedestals of the columns, perhaps as much for the purpose of proportioning the apertures, as for the formation of a parapet. When columns are destitute of pedestals, they should stand upon a plinth, that the bases may be kept dry and clean, as well as to prevent them from being broken.

The Romans employed arcades in their triumphal arches, and in various other buildings. They may with great propriety be adopted for gates of cities, palaces, gardens, or parks, and are much used in the piazzas or squares of Italian cities. In the latter, they are of great utility for the purposes of shade and shelter in hot or rainy weather, but they darken the apartments of the houses, and, in these northern climates, render them very uncomfortable.

Basement.

Basements. This term is applied to the lower story of a building, whether on a level with, or below the surface of the earth. The height of the basement is determined by its being the cellar or the ground story, or as there may be principal rooms in one or both of them. It should never, however, exceed that of the story next above it, for this would invert the order of the edifice, by making the base of more consequence than the body supported by it.

When the basement consists of the cellar story, it should not exceed five, but at most six feet in height above ground, and may be either plain, rusticated, or formed into a continued pedestal: but when it forms the ground story, it is customary to decorate it with rustics, supported on a base, and surmounted with a crowning string course. The base itself may be either a plinth simply, or a plinth with mouldings over it; the string course, likewise, may be a plain platband, or a platband with mouldings under it; or it may form a cornice.

Rustics.

The rustics are formed of a rectangular or a triangular section, by imagining one of the sides of such section to be a line extended across the front of the joint. The joints of the rustics may be from an eighth to a tenth part of their height. Triangular rustics may have the depth of their joints half their breadth; that is to say, making the two planes by which the joint is formed a right angle. The depth of the joints of rectangular rustics, may be from one-fourth to one-third of their breadth.

Both directions of the joints were marked by the ancients; but the moderns frequently make their rustics with the horizontal joints only; in which cases, they seem rather to represent a boarded surface than a stone wall, whose very nature indicates two directions of joints.

String course.

The string course should never exceed in height that of a rustic with its joints; nor should the socle, or plinth, be less than that of the string course. When the string course is a cornice, the base may be moulded; in such cases, the cornice may be about an eighteenth part of the height of the basement, and its projection about two-thirds of its own height, so as to be less prominent than that with which the building is crowned. The base may be twice the height of the cornice, and being divided into six parts, the lower five may form the plinth, and the remainder be occupied by the mouldings.

Imposts.

When the basement is perforated with arcades, the imposts of the arches may be a platband, equal in height to that of a rustic without its joint.

Pedestal.

Pedestals are used for supporting a colonnade or a pilastrade; and sometimes they supply the office of a basement to a building. They consist of a base, surmounted with a rectangular prismatic solid, called *the die*, crowned with a cornice.

None in ancient Greece, except the temple of Theseus.

The use of pedestals appears to have been an innovation subsequent to the loss of political independence in Greece. In the original examples of Grecian architecture, we find the columns standing on the uppermost of three steps; a rule, to which we know of but one existing exception, to be seen in the temple of Theseus at Athens, which has but two steps. The Romans, however, when they raised the floors of their temples and other edifices high, were under the necessity of discontinuing the front stairs, lest they should prove inconvenient by occupying too much ground around the building, and of adopting the pedestal or podium, raised to a level with the top of the stairs, and projecting to the front of the steps which profiled on its sides.

Vitruvius, in treating of the Doric, Tuscan, and Corinthian orders, makes no mention of a pedestal; and, in treating of the Ionic, speaks of it as a necessary part of the construction, but not as part of the order.

Wherever pedestals are introduced, the grandeur of the order is diminished, as all the parts are proportionally reduced; yet are they indispensible in some situations, as in the interior of modern churches, where, without them, the beauty of the columns would be lost, through so large a portion of them being hidden by the enclosures of the pews.

Proportions variable in Rome.

In ancient Roman buildings, the proportions of pedestals are very variable; but some modern writers have endeavoured to reduce them to a regular standard. Vignola would have them to be one-third of the altitude of the column; but as this appeared to make them too high, Sir William Chambers reduced it to three-tenths; but both ratios must be subject to variation, according to circumstances: Pedestals still lower are to be preferred.

The parts of pedestals may have the following proportions, which may be considered as common to all: Divide the whole height into nine equal parts, and give two to the base, six to the die, and one to the cornice. The base may be subdivided into three parts, of which the plinth may have two, and the mouldings one, which may in general have a projection equal to their height. The plan of the die must be similar to that of the plinth of the column; and the projection of the cornice may be equal to its height.

As to the decorations of pedestals, projecting tablets are inadmissible. It is sometimes customary to adorn the dies with sunk pannels, surrounded with mouldings; and the pannels themselves are occasionally occupied by bas-reliefs or inscriptions. The dies of the pedestals in the arches of Septimius Severus, and of Constantine, have straight-headed niches, containing statues.

Pedestals should never be insulated, though the columns sustained by them be so. In the ancient theatres and amphitheatres, the inferior orders rested on steps, while all the superior orders stood upon pedestals, which formed a parapet for raising the base of the order sufficiently high as to be seen on a near approach to the building, and for the spectators to lean over; but they never exceeded the height necessary for the prevention of accident.

When pedestals were continued with breaks under the columns, or pilasters, in ancient buildings; the breaks were termed *stylobatæ*, and the recess between every two stylobatæ, *the podium*; and both had the same parts disposed at the same levels.

Pediments.

Pediments. These ornaments probably owe their origin to the inclined roofs of the primitive huts. They consist of a horizontal cornice, representing a tie-beam, and two others of equal inclination over it, indicative of rafters, or the latter are exchanged for an arched one. The surface included within these cornices is called *a tympanum*; which, of course, is either a triangle or the segment of a circle. This definition does not include all those species of pediments which have been introduced, perhaps with more fancy than genuine taste, into modern buildings, but only those of the ancients, who, in most things, were close imitators of the prototypes from which they borrowed their designs. In the true pediment, therefore, we only see a representation of the end of a roof whose purpose was to discharge the rain from the the centre of the building, by leading down to the extremities, there to be discharged over the flanks, and not over the front, as must be the case in every figure that can be introduced, except those of a polygonal form, which present their interior angles to the horizontal cornice, or upwards to those of the exterior.

Plates CLVII. CLVIII.

In the antient buildings of Greece, (see Plates CLVII. and CLVIII.), we find only the triangular pediment; but in those of Rome, both triangular and circular are to be met with; and in rows of openings, or niches, both kinds are employed in alternate succession. Though they seem to have preferred the triangular form for doors, windows, and gates, and to have applied the circular pediment to the covering of large or small bodies promiscuously.

Pediments, among the Romans, were exclusively appropriated to sacred edifices, till Cæsar obtained leave of the senate to cover his house with a pointed roof, after the manner of the temples.

The ancients introduced but few pediments into their buildings; even the Romans, usually contenting themselves with a single one to adorn the middle or principal part. But some of the moderns, and the Italians in particular, have become so immoderately fond of them, that sometimes their buildings can hardly be said to consist of any thing besides.

Rule for pediments from Vitruvius.

Vitruvius has given the following direction for finding the pitch of a pediment: "Divide the space between the extremities of the cymatium of the corona into nine equal parts, and take one for the height of the tympanum." This rule, however, is incorrect; because the tympanum will vary its angle according as there are more or less mouldings of the inclined cornices within the extremities of the cymatium of the corona; and since, by this rule, the middle part is invariable, and the broader the parts are of the inclined cornices within each extremity of the cymatium of the corona, (or rather within the under edge of the fillet of the sima upon each inclined cornice), the less will be the base of the tympanum; consequently, the three angles will be less acute. But were this height extended to the meeting of the two under sides of the fillets of the sima, or crowning moulding, the figure of the tympanum would be invariably the same.

The foregoing rule of Vitruvius has been considered as too low; but it must be recollected, that that of the octostyle portico of the Parthenon at Athens, is nearly of the proportion there described; that of the hexastyle portico of the temple of Theseus, is about an eighth; that of the Ionic temple on the Ilyssus, and of the Doric portico, which are both tetrastyle, are about one seventh; and the tympanum of the pediment over the door of the tower of the Winds, is about one-fifth of the span; all which edifices are Athenian.

From this comparison, a kind of reciprocal ratio seems to exist between the extension of the base of the tympanum and its height; and, indeed, were a fixed ratio applied to windows, the pediment would frequently consist of a cornice only, without any tympanum. It is, therefore, with good reason, that the pitch of pediment windows is frequently made greater than of such as crown porticos or the fronts of buildings.

Pediments are sometimes decorated with plinths, called *acroterions*, or *acroters*; of which, Vitruvius observes, the two presenting triangular faces at the extremities, each in height half that of the tympanum, and the middle one, saddled on the summit, is one-eighth higher than the others.

It is an observation of Vitruvius, that "the Greeks never used mutules, modillions, or dentils, in the front, wherein the end of the roof or fastigium appears; because the ends of the rafters, and of the laths which support the tiles, only appear at the eaves of the building; and as mutules and dentils originated from the projecting ends of the rafters and laths, it would have been absurd to introduce them into the pediment, where the exemplars are themselves to be seen." But, just as this argument is, we find in the Grecian remains, that though neither mutules, dentils, nor modillions, are employed in the sloping sides, mutules are constantly used in the horizontal cornice. In edifices of the period of Roman domination in Greece, indeed, we sometimes may observe them in the sloping cornices, but they must be considered as innovations. At Rome, we have examples of modillions in the Pantheon, and in the frontispiece of Nero; and in the temple of Fortune, dentils are used. In the inclined cornices, the sides of the modillions and dentils are planes perpendicular to the horizon and to the front of the edifice, and in the same vertical planes of those of the horizontal cornice.

Attics.

Attics. Among the Athenians, it was a rule to conceal the roofs of their buildings, for which purpose they crowned their cornices with low square pillars, of a form nearly approaching that of a pedestal, which have obtained the appellation of attics, from the country in which they were first, or chiefly employed, though no remains are now to be discovered among the ruins of the ancient city of Athens.

Roman attics are to be seen in the remains of the triumphal arches, and in the piazza of Nerva. In the arch of Constantine, the columns are surmounted with pedestals, as high as the base of the attic, upon which are placed insulated statues. At Thessalonica, there is an attic over a Corinthian colonnade, with breaks forming dwarf pilasters over the columns, as in the arch of Constantine. The attic which is carried round the two courts of the great temple of Balbec, is also broken into dwarf pilasters over the columns and pilasters of the order; which dwarf pilasters are surmounted with blocking courses, wherein statues are supposed to have stood.

In all these remains, the attics are disproportional; some of them being nearly one half of the height of the order. The moderns make their height equal to that of the entablature; and the proportion of that of the members may be regulated as in the case of pedestals.

Niches.

Niches. These decorations consist of recesses in a wall, either for the purpose of embellishment, or for receiving statues or other ornaments. They may be formed with spherical heads, and cylindrical backs, or entirely with hemispherical backs, or with spheroidal backs, having the transverse or conjugate axis of the ellipses vertical, as may best comport with the character of the object to be placed therein. Those with spheroidal backs may have their horizontal sections in circles of different diameters, and consequently, their sections through the vertical axis, all equal semi-ellipses, similar to each other; or all their horizontal sections may be similar ellipses, and the sections through the vertical axis of the niche will be dissimilar ellipses of equal heights, at least for one half of the niche; but spheroidal niches with such sections are difficult of execution, and more pleasing to the eye than those with circular horizontal sections. Among the works of the Romans, niches have either a circular or rectangular plan; the heads of those of the circular kind are generally spherical. In the middle of the attic of Nerva, at Rome, a niche is seen with a rectangular elevation, and a cylindrical back and head. Those upon elliptic plans were not much used by the ancients; though in Wood's "Ruins of Palmyra," there are two niches with elliptical heads, within the entrance portico of the Temple of the Sun; but the author has given no plan of them. Most frequently, those upon rectangular plans, have horizontal heads, though a few are to be met with that have cylindrical heads: those upon circular and rectangular plans, are, for the sake of variety, most commonly placed alternately.

The plans of niches with cylindrical backs, should be semicircular, when the thickness of the walls will admit of it; and the depth of those upon rectangular plans should be the half of their breadth, or as deep as may be necessary for the statues they are to contain: their heights depend upon the character of the statues, or on the general form of groups introduced, yet seldom exceeding twice and a half their width, nor being less than twice. Those for busts only, should have nearly the same proportion in respect to each other. In some cases their height may rather exceed the measure of their breadth: they may be of any of the forms used by the ancients, or of those mentioned at the beginning of this article.

In point of decorations, niches admit of all such as are applicable to windows; and whether their heads be horizontal, cylindrical, or spherical, the enclosure may be rectangular. In antique remains, we frequently meet with tabernacles as ornaments, disposed with alternate and arched pediments; the character of the architecture should be similar to that placed in the same range with them.

Niches are sometimes disposed between columns and pilasters, and sometimes ranged alternately, in the same level with windows: in either case they may be ornamented in plain, as the space will admit, but in the latter, they should be of the same dimensions with the aperture of the windows. When the intervals between the columns or pilasters happen to be very narrow, niches had better be omitted, than have a disproportionate figure, or be of a diminutive size.

When intended for containing statues, vases, or other works of sculpture, they should be contrived to exhibit them to the best advantage, and consequently the plainer the niche, the better will it answer the design, as every species of ornament, whether of mouldings or sculpture, has a tendency to confuse the outline.

Remarks.

Having described the several parts of which the buildings of the Greeks and Romans were chiefly composed, we shall proceed to give some account of the principal edifices in which they were introduced, leaving the investigation of the other parts of practice, which relate more immediately to modern works, till we come to speak of the revival of Roman architecture in Europe. The edifices now to be treated of are ancient temples and villas: Their places of public exercises and amusements are referred to other articles in this work.

Of Greek Temples.

Greek temples.

The Greek temples were all of an oblong form, with an entrance in the middle of one or both of the shortest sides. The roofs were generally continued (except in the hypæthral) in the direction of the longest sides, terminating at gable ends or pediments, raised in the shape of the roof upon the shortest sides or ends. One of the orders of architecture was usually employed upon a part or the whole of the edifice. They were distinguished into different sorts, either from some parts of the general form, or the number or distribution of the columns, or the distance at which these were placed from each other.

Denominations.

1. When a part of the inside space next the walls was covered with a roof, and the middle left uncovered, the temple was named *Hypæthral.*

2. When there were columns only at the end where the entrance was, the temple was named *Prostyle.*

3. When there were columns at both ends, the temple was named *Amphiprostyle.*

4. When there were columns at both ends, and also along each side, the latter being placed at a distance from the outside of the walls equal to that between those at the ends, and the columns at each angle standing in a line with, and being common to each row in the adjoining sides, the temple was named *Peripteral.*

5. When along each side there were two rows of columns at a distance from each other, and the inner row from the walls equal to the distance between the columns at the ends, all the other circumstances remaining the same as in the preceding definition, the temple was named *Dipteral.*

6. When all the circumstances in the two immediately preceding definitions remain the same, only the inner row of columns on each side being removed, the temple is denominated *Pseudodipteral.*

7. When there are columns at each end, and the sides have attached columns, projecting only half or a greater part of their diameter, the temple is named *Pseudodipteral.*

8. When the side walls are continued, so as to be in a line with the column at one or both ends, so as to occupy the place of the angular columns, by supporting the entablature, the end of each projecting wall being terminated by vertical rectangular prisms, having mouldings in place of a capital at the top, the temple is said to be *in Antis.*

Temples also receive appellations from the number of columns placed at one or both ends, and in all those of Grecian origin, with the exception of that at Pæstum, (which has nine) the number is always even. When there are 4, 6, 8, or 10, the temple is said to be *Tetrastyle, Hexastyle, Octostyle,* or *Decastyle.*

The temple *in antis,* had usually only two intermediate columns.

The prostyle temples were generally tetrastyle, or with four columns.

The hexastyle and octostyle were generally peripteral, though there is an exception in the octostyle temple of Bacchus at Teos, being pseudodipteral.

The decastyle peripteral temples were generally hypæthral, but the Parthenon at Athens is octostyle hypæthral. This arises from its great breadth.

Temples had also names depending on the distance at which the columns were placed from each other. The interval is called intercolumniation, and is measured by the lower diameter of the shaft. When it is 1½ diameter, it is named Pycnostyle; when 2, Systyle; when 2¼, Eustyle; when 3¼, Diastyle; and when 4, Aræostyle. Of all these, the eustyle has been most generally practised both by the ancients and moderns.

Pronaos and posticum.

The space between the columns and wall at the entrance or front end, is denominated pronaos. The similar space at the opposite end, the posticum. The space within the walls was called the cell.

In the hypæthral temples, besides rows of columns along the outside, there were also rows within the cells, and these were placed sometimes along each of the four sides, and sometimes along the longer sides only. These were necessary to support the roof, and were named Peristyle. In some instances, as in the temple of of Minerva at Tegea, and at Pæstum, the inner rows consisted of two heights of columns; but it is proper to observe, that, in both these specimens, the upper rows have, by judicious persons, been ascribed to the Romans.

Peristyle.

In the application of the Doric order to temples, the intercolumniation was regulated by the triglyphs. Where there was only one between the columns, the mode was denominated monotriglyph, and it was almost the only one employed in the Grecian edifices.

General remarks.

In the Greek temples, the number of columns along each flank or longer side, was always one more than double the number along the front, or shorter side; that is to say, if there were eight columns along the front, there were seventeen along the flanks, counting the angular columns both in the front and flank ranges. These temples were raised upon an artificial platform, ascended by three steps, which surrounded the whole building. The outer row of columns, which stood upon the upper step with their accompanying entablature, also surrounded the building without a single break. The pediments upon the ends, the whole of the frieze along the columns, and likewise that along the walls under the portico, were frequently filled with the most exquisite sculptures.

We shall now proceed to produce some examples from Greek temples which still exist; and as works executed under the influence of Pericles, and the immediate direction of Phidias, must exhibit the essence of Greek taste, we have selected those formed in the Acropolis at Athens, as faithfully measured and delineated by Messrs Stuart and Revet, and which fortunately afford perfect specimens of the Doric, Ionic, and Cariatides.

Minerva Panthenon. PLATE CLVII. Dimensions.

The magnificent temple, dedicated to Minerva Parthenon, (see Plate CLVII.) which stood within the Acropolis, was 225 feet in length, and 100 feet in breadth, measured on the top of the third step which surrounded the building. There were eight Doric columns in each front, and seventeen on each side, counting those at the angle twice. They were without bases; the row which surrounded the whole buildings were those at the angles 6 feet 3.5 inches, all the others 6 feet 1.8 inches diameter; and, including the capitals, were 34 feet 2.8 inches high. The intercolumns, next the angles, were each 5 feet 8.8 inches, all the others 7 feet 11.5 inches. The height of the architrave was 4 feet 5.1 inches, and of the frieze, including the cap of the triglyph, the same. The height of the cornice, exclusive of the top member, 2 feet 4.6 inches. The depth of the spandrel of the pediment, at the middle, 11 feet 6 inches. The inner row of columns in the portico at each end, stood two steps higher than the outer row. These steps also passed quite around the cell. The diameter of these columns was 5 feet 6.5 inches. The distance from centre to centre of those next the antæ was 12 feet 0.3 inch; of the others 13 feet 9 inches. The breadth of the front of the antæ 4 feet 11.7 inches. A peculiarity here was, that the inner row of columns stood before the antæ; whereas, in other temples, they usually had the antæ in a line with them. The column shafts were fluted. The flutes were shallow, and met in a sharp edge. They reached from the bottom of the shaft to the underside of the cap; and here were cinctures in place of astragals. In the soffit of the entablature were mutules, with 18 drops in each. The soffit, at the external angles, was decorated with honeysuckles. All the metopes in the frieze (92 in number) have been enriched with sculpture. Those on the south side have each a groupe, representing a Centaur combating a Lapitha; they are in the finest alto relievo. Those on the northern sides and two fronts were more defaced. On the frieze, under the porticos, which encompassed the cell, and measured 520 feet in length, and 3 feet 4 inches in height, was represented the Panathenaic procession. Sixty feet on each side have been occupied by horsemen, who attend the festival. They were preceded by charioteers. In the last is a youth, supposed a victor in the chariot races. A man is about to crown him. There are also sacrifices. On the eastern pediment was an assemblage of the gods, in which Jupiter appears to be receiving Minerva, and acknowledging her as his daughter. On the pediment at the other end was represented Minerva's contest with Neptune. From the front of the inner columns to the front of the wall of the cell, the distance is 17 feet 6.2 inches. The thickness of this wall is 6 feet 7.9 inches. The entrance doorway is 12 feet 6.75 inches wide, and 28 feet 8 inches high. Here is an ascent of about one inch into the Pronæus, which had been covered and supported by six columns, viz. three on each side. It was the Opisthodomas, or place where the public treasury was kept. The length 43 feet 9.75 inches; the breadth 62 feet 6 inches. From this apartment was a doorway of equal breadth to the former, which opened into the great apartment, 98 feet 7.25 inches in length, and 62 feet 6 inches in breadth. The wall, which divided this from the Pronæus, was 2 feet 11 inches thick. The side or outer walls each 3 feet 10.3 inches. A space 15 feet in breadth along the sides, and 14 at each end, was covered and supported by a row of columns. The middle space between these columns was open, and sunk about one inch below the level of the sides. It was in this division that the famous statue of Minerva stood. Wheeler and Spon, who visited Athens in 1676, being 11 years before the Venetians destroyed the roof, saw within the cell, on each side, two rows of columns, one above another, standing at some distance from the wall. The decorations of the eastern front prove it to have been originally the principal entrance. Under Phidias, the architects were Callicrates and Ictinus. It was built of Pentilic marble; and the inimitable sculptures which adorned its pediments and friezes, partly acquired to this country by the exertions of Lord Elgin, shew the degree of perfection to which the Greeks had carried that art, (see ATHENS.) Reflections have been cast on that nobleman, for thus de-

Sculpture.

Architects.

Exertions of Lord Elgin.

priving this splendid ruin of its appropriate decorations. If it had been possible to have preserved it inviolate, he would have undoubtedly been blameable; but when it is considered that the hand of ignorant barbarism had already, during a recent period, converted one inimitable structure into lime for mortar, and materials for constructing filthy huts; and had also laid sacrilegious hands upon the Parthenon itself; and that depredations had likewise been commenced by a power, which, from its extensive spoliations in other quarters, left no room to doubt its intentions here, this active nobleman, instead of being exposed to censure, ought to receive the warmest acknowledgments of the British artists and nation.

In the preface to the third volume of Stuart's Antiquities, by Revely, we learn that the columns of the Temple of Minerva were composed of single blocks in thickness; that each course was somewhat more than one diameter high; that the wall inclosing the cell was formed of a single row of marble blocks in thickness; that the vertical joints alternately corresponded; that from the top of the upper step to the bottom of the architrave, being 33 feet, there were 17 courses; that each capital was of one block, 2 feet 9.9 inches high; that the architrave lies upon them without any other precaution than perfect accuracy. The architrave consists of three blocks in thickness, each reaching from centre to centre of the columns. The frieze is in two courses in height, and each of them so much short of thickness, as to admit the metope, a thin slab, to be placed against it. The triglyph tails in, in one height, but does not go through. The cornice is in blocks, which are the width of one mutule and one space, their ends forming a complete course in the inside. The tympanum of the pediment is formed of one course of upright slabs on the outside face, with horizontal courses behind them. The pavement is formed in squares of equal size; they are large and thick; the joints, as in the universal practice at Athens, are so neatly fitted, as scarcely to be discernible.

Minerva Polias, Erechtheus, and Pandrosus.
Plate CLVII.
Ionic order.
Cariatides.

Adjacent to the Parthenon stood the singular and beautiful structure, which contained the temples of Erechtheus or Neptune, of Minerva Polias, (or protectress of the city,) and that of Pandrosus, one of the daughters of Cecrops, (see Plate CLVII.) The principal mass of the building was of an oblong shape, with a portico of six Ionic columns at one end to the temple of Neptune, and four of the same order to that of Minerva. There was also another portico of six Ionic columns, which projected partly from the side, and partly extended beyond one angle of the temple of Minerva. Opposite to this, on the other side of the last mentioned temple, was a small projection which composed the temple of Pandrosus; and the front of this projection was supported by Cariatides. The floor of the temple of Neptune was about eight feet above the level of the other two. This irregularity of height and shape produces a fine effect, as will be observed by consulting Plate CLVII. The columns of the portico of the temple of Neptune, including the base and cap, are 21 feet 7.8 inches high, and 2 feet 3.8 inches diameter. The intercolumns, from centre to centre, are 6 feet 11.2 inches. Distance from the centre of column to the face of the wall 6 feet 5 inches. The columns of the temple of Minerva are 22 feet 10 inches high, and 2 feet 9.34 inches diameter. The intercolumn, from centre to centre, is 10 feet 3.6 inches. The shafts of the columns are fluted, and the neck of the caps enriched with honeysuckles. The caps are also enriched, as is one member of the architrave and two of the cornice. The same enrichment, as on the neck of the capitals, is carried along the sides of the cell under the general architrave, being a continuation of the cap of the antæ. The base, capitals, and entablature of the portico to the temple of Minerva are beautiful. The upper torus of the base of the column is enriched with a Guilochi. The base nearly resembles the attic, only the lower torus and plinth have more projection, which adds to the apparent stability. The capitals, at the external angles, have each a horn, like the modern Ionic. The height of the architrave is 2 feet 1.25 inches. The frieze 2 feet 2.6 inches. Level cornice of pediment only 11.3 inches. The windows to the Pronaus, which light the temple of Minerva, are 6 feet 4.36 inches in height; they are 3 feet 1.1 inch wide at the bottom, and 2 feet 10.35 inches at the top. The architrave stands on a sill at the bottom, and has a break on each side at the top. The height of the Cariatides, in the temple of Pandrosus, is 7 feet 9.15 inches, including the caps. The figure only 7 feet 1.05 inches. The entablature they support is 2 feet 11.8 inches. It is very heavy, but highly enriched. This is the only ancient temple in which the entablature is supported by Cariatides. In the temple of Minerva Polias was placed the celebrated golden lamp, made by Callimachus, the inventor of the Corinthian capital. This temple was burnt by Xerxes. The inscription, published by Dr Chandler, contains a survey of the parts which remained to be completed in the 23d year of the Peloponnesian war. The estimate of the expence was from £300,000 to £400,000 sterling. Hence, it is not improbable, that this structure was begun during the administration of Pericles, and a stop put to it by his death, or by war.

Plate CLVII. Dimensions of order.
When completed.

Temple of Theseus.

The temple of Theseus at Athens, was one of the finest remains of the age of Pericles. It was entirely built of Pentilic marble. It was a peripteros of the Doric order. The total length upon the upper step was 104 feet 2.9 inches; the breadth 42 feet 2.95 inches. The portico consisted of six fluted columns, and 13 on each side, counting those of the angles twice; the height including the capital, 18 feet 7.18 inches; the diameter, 3 feet 3.4 inches; the intercolumn 5 feet 3.95 inches, and 5 feet 4.05 inches, and next the angle 4 feet 6.35 inches. The height of the architrave was 2 feet 8.9 inches; the frieze, 2 feet 8.53 inches; the level cornice, 1 foot 0.45 inches. The metopes and frieze under the portico were enriched; there is also a very rich Guilochi over the latter. The principal front faced the east; here the pediment was filled with exquisite sculpture in alto-relievo, fixed in their places by metal cramps. In the metopes, in this front, were represented the labours of Hercules; and in the four metopes next this front, in the north and south sides, were the labours of Hercules. The length of the cell, exclusive of the portico, pronaus, and posticum, was only 39 feet 9.2 inches, and the breadth 20 feet 4 inches.

Temple of Corinth.

The only temple at Corinth of which there are any remains, is of the Doric order, evidently before the age of Pericles. It is built of a rough stone. The height of the column, including the capital, is 23 feet 8¼ inches; the diameter 5 feet 7 inches. The shafts have each been of one stone; they begin to diminish from the bottom. They have 20 flutes, which terminate under the listil of the cup; they are segments of circles. The height of the architrave, including the bands over the drops, is 4 feet 9¼ inches. The guttæ are round and detached from the architrave; there are six drops under the triglyphs.

Temple of Ceres at Eleusis.

From Dr Chandler we learn, that the temple of Ceres at Eleusis, was erected under the direction of Pericles, from a plan of Ictinus, one of the architects of the Parthenon. It was situated at the east end, and under the brow of a hill, and was encompassed by the fortress. The length, including the pronaus or portico, was 216 feet; the breadth of the cell about 150. The temple was originally *in antis*, or without exterior columns. Under Demetrius the Phalerian, the celebrated architect Philo added a magnificent portico, the outer row of which consisted of ten, and the inner row, between the antæ, of eight Doric columns. They were 6 feet 6 inches in diameter, and fluted, commencing six inches from the bottom of the shaft. From the inside of the column to the face of the wall, the pronaus was 42 feet 6 inches deep, and about 140 feet in width. The columns on the pavement within, and their capitals, were by Corætius. Metagenes of Xypate added the architraves on the upper pillars, which sustained the roof. It is said that another person completed the edifice. The peribolous, or enclosure which encompassed the north-east and south sides, was 387 feet from north to south, and 328 from east to west. On the west side it joined the angles of the temple. Between the west wall of the enclosure and the temple, and the wall of the citadel, was a passage 42 feet 6 inches wide, which led to the summit of a high rock. At the north-west angle of the enclosure are the traces of a temple *in antis* 74 feet 6 inches long, and 54 wide, probably sacred to Triptolemus. North of the enclosure are marble fragments of the Doric and Ionic orders, thought to be the remains of the temples of Diana Propylea, of Neptune, and of the Propyleum, or gateway.

Jupiter Olympus at Elis.

The temple of Jupiter Olympus, at Olympia in Elis, from a design of the architect Libon, was of the Doric order, 231 feet long, 96 broad, and 68 high. On one pediment, Oenomans and Peleus were disputing the prize of the race in the presence of Jupiter; on the other was the battle of the Centaurs and Lapithæ. On the summit of each pediment was a Victory of gilt brass; and at each angle a large vase of the same metal. The labours of Hercules decorated the gates, in the Doric temple of Jupiter Olympus at Girgenti, the ancient Agrigentum, which were more than 12 feet diameter. Those of Silenus, now remaining, are ten feet.

Diana at Ephesus.

The celebrated temple of Diana at Ephesus, constructed at the joint expense of all Asia, was of the Ionic order, and designed by Ctesiphon the Cnosian, and his son Metagenes, who wrote a treatise upon it. It was situated at the foot of a mountain and the head of a marsh, a place chosen, in Pliny's opinion, as least subject to earthquakes. In order to protect the site of the structure, drains were constructed to collect and convey the water along the skirts of the mountain. By the same author we learn, that, in order to render the foundations secure, they first laid a thick bed of charcoal well rammed, and upon that one of wool; and that the quantity of stones employed in the foundations of the edifice and drains was such as to require quarries so extensive as to be in after ages taken for a labyrinth. The temple was 425 feet in length, 220 in breadth, and 70 in height. It had a double row of Ionic columns along the flanks of the cell. In page 361 of Wren's *Parantalia*, are the following observations respecting this structure. "The columns being sixty feet high, the diameter, according to rule, must be 6 feet 8 inches, that is, one-ninth part. Thus every column would contain 110 tons of marble, besides base and capital; and the vast stones of the entablature, but more especially of the middle intercolumn, which being wider than the rest, to open more way for the entrance, as usual in Greek temples, was about 22 feet, and could not bear its own weight, unless the architrave and frieze were of one stone, which together would be above 150 tons; the setting of which (for it seems the architect despaired) was miraculously attributed to the goddess herself, as beyond the reach of human skill. Thirty-six of the columns were by the hands of Scopas, a famous statuary of the school of Praxiteles; and the outward walls of the cella were adorned with pictures about the time of Apelles." According to Pliny, 400 years were employed in constructing this temple.

Diana at Magnesia.

In the Ionic temple of Diana at Magnesia, designed by that Hermogenes whose merits are highly extolled by Vitruvius, the general dimensions are the same as the Dipteros; but having, in order to obtain more free space under the flank porticos, omitted the inner range of columns, he thereby established the pseudo-dipteros; but unless he continued the wooden beams of the roof over this increased space, this mode was impracticable, unless when the quarries afforded marble blocks of very large dimensions.

Minerva at Tegea.

In the magnificent temple of Minerva at Tegea, designed by Scopas, the peristyle which surrounded the temple consisted of columns of the Ionic order; but in the cell, which was divided into three aisles by two rows of columns, each row consisted of two heights, the lower range being of the Doric, and the upper of the Corinthian order; and this is the only instance in which two different orders are placed one above the other in a Greek temple. And where the Corinthian order is at all introduced, these circumstances have induced an able critic (Knight *On Taste*, p. 178.) to suppose, that these upper columns have been, during a repair of the edifice, raised after the Roman conquest. In this temple, the sculpture in both pediments was by Scopas; the subject of the one was the hunting the wild boar of Caledon, in which the figures of Hercules, Theseus, Pirothous, and Castor, were conspicuous; on the other pediment was exhibited the combat of Achilles and Telephus.

Jupiter Olympus at Athens.

There is no vestige of any temple in Greece of the Corinthian order previous to the Roman conquest; for the temple of Jupiter Olympus at Athens, though begun by Pisistratus, was built under the reign of Hadrian, by Cossutius, a Roman citizen (*Vitruv.*). Its length, measured on the upper step, was 354 feet 2 inches; the breadth 171 feet 2 inches. There were ten columns in the outer rows, at each end; and 21 along each side, (counting those at the angles twice). Their diameters were 6 feet 6.85 inches, and 6 feet 4.332 inches, and the height 60 feet. The shafts were fluted, but not to an edge. The bases were attic. There was one row of columns along each side, in the inside of the cell. The length of the court which encompassed the temple was 688 feet 6.5 inches; the breadth 463 feet 5.87 inches. But this magnificent work cannot be termed Grecian.

General remarks.

Having explained the several denominations under which the Greek temples were known, and given some account of ten of them, we conceive it quite unnecessary to pursue this part of the subject further, especially as the elementary parts have already been discussed and illustrated in treating of the different orders, &c.; we shall therefore now proceed to give a description of a Greek house and villa.

Private houses.

The Greek houses generally consisted of two sets of apartments; the upper story for the women, the lower for the men. The roofs had terraces, with a large projection at each extremity. A considerable number had gardens behind them, and a small court in the front, or rather a sort of portico, at the end of which there was a door. At this place there was always either the figure of Mercury or a dog, to frighten thieves; also an altar to Apollo, upon which the master sacrificed on certain days. In process of time, wings were added to the houses, and the apartments of the husband and wife were both placed on the same floor.

The house of Ulysses, which must have been the palace of Ithaca, had a court before it, surrounded by a stone-wall with a coping. In this the gateway had folding doors; but there appears to have been only one apartment for receiving and entertaining strangers; and in this the slaughtering and cooking were likewise performed. It was entered immediately from the court. One stair led from it to the roof, and another to the storerooms, or perhaps the bedrooms. The floor was below the level of the threshold, and was paved with stone. The windows must have been very high, as the suitors, when attacked, could not reach them. The area of this apartment must have been very extensive, but we have no data for ascertaining the precise dimensions.

Plate CLXI.

In Plate CLXI. taken from Palladio's explanation of the description given by Vitruvius, it will be seen, that the Greeks, in their most magnificent villas, had no vestibule adjacent to the street, but a narrow passage, or gateway, on one side of which were stables, and on the other porters' lodges. From this passage there was an entrance to the peristylium, which had porticos on three sides. On the side facing the entrance, or that which looked towards the south, there was no portico, but a wide aperture, with antæ on each hand, which led into an oblong porch. On the right and left of these were three apartments on each side, called antichamber, chamber, and backroom. Behind these were apartments for the women and their attendants; and round the portico were rooms for dining, sleeping, and servants' rooms. Behind this edifice was another still more magnificent suit of apartments, appropriated wholly to the men. Here the peristylium was of greater extent, and the rooms more spacious and highly decorated. The porticos of this peristylium were four: They were sometimes all of an equal height; and sometimes three of them only, the fourth, or that on the north side, being higher than the rest. The dining-room fronted the north, as did the rooms for pictures. Those for conversation, or sleeping, looked to the west, and the libraries toward the east.

Apart from all these edifices, on either side, the lodgings for strangers were separated by passages, and were entered by distinct gates. They consisted of complete suits of apartments, with store-rooms furnished with provisions; and here, after the first day's visit, they resided in a separate dwelling.

Of Roman Temples.

Roman Temples.

The Romans did not, like the Greeks, adhere to simplicity in the form of their temples; they, on the contrary, deviated into every shape, even to complicated combinations of circles and triangles; but as it would be as endless as useless to notice such frivolities, we shall only select a few of the best specimens, which were either of an oblong or circular form.

Temple of Peace.

Of those, in which the outlines inclosed an oblong space, the great temple of Peace at Rome is the most noted example; and this was likewise the largest of the Roman temples. In our descriptions and dimensions of this, and also the other ancient remains at Rome, we shall be chiefly guided by Desgodetz, who seems to have been at great pains in measuring and delineating them with accuracy.

This temple was begun by Claudius, and completed by Vespasian; who, when he had subdued Judea, placed there the spoils of the Jewish temple. (See Plate CLXIV.) It was in length fifty-six fathoms, (336 French feet), and forty-three fathoms (258 French feet) in breadth; at the entrance, there was a lobby or porch of the same breadth as the temple. This porch had five entrances, of which three led immediately into the great middle division or nave; the other two opened into the side divisions or aisles, which were not carried up so high as the nave. The breadth of the nave was 77 feet 5 inches, and each side aisle 48 feet. The ceiling or roof of the nave was an immense groined vault, which rested upon eight Corinthian columns. The aisles had also vaults lengthwise, which were intersected by others, that covered the recesses or chapels which projected outward from their side walls. The middle recess of the aisles, as well as that at the end of the nave, were circular like large niches, and nine fathoms wide. The recesses, which have not large niches, have two rows of arched windows in them, three in each row; there is also over each recess a large window, five fathoms broad. The soffits of all the vaults, and also the coverings of the niches, are ornamented with octagonal sunk pannels, formed with stucco. Excepting the entrance, which had a portico composed of columns and a pediment, all the outside was quite plain. We are informed by Desgodetz, that the only remaining column, (we suppose he means of the portico), was removed by Pope Paul V.; it stands before the church of St Mary Major, supporting an image of the Virgin in bronze. It is of white marble, of the Corinthian order, 5 feet 8¼ inches (French) diameter at the bottom; the shaft (of one piece) is 49 feet 3 inches high. The architrave and cornice are enriched; the frieze is plain.

Plate CLXIV.

Groined arches.

Montfaucon says, that this temple was 340 feet long by 250 broad, that the portico was 240 feet long by 30 broad; that there were eight columns in front, each 8 feet 9 inches diameter. Serlio gives a plan with eight small columns, viz. two on each side of four niches; and Laurus gives an elevation with only six columns; so that there seems to be very little certainty as to the portico. Beside the Jewish temple, Egypt contributed to enrich this repository of spoils; for within it was placed the celebrated groupe of black marble, representing the Nile and sixteen children, expressive of the sixteen cubits rise of that river. In the time of Commodus the inside was burnt by an incendiary.

Square house at Nismes.

Though of much smaller dimensions, the square house at Nismes, and the temple of Fortuna Virilis at Rome, are more in the Greek manner, their general form being oblong without any breaks. The former was built by Hadrian; it is 74 feet long, and 41 in breadth; the portico consists of six fluted Corinthian columns in front, and three in depth; on the flanks, counting those at the angles, there are eleven columns, but those opposite the sides and arriere end of the cell, are only semi-columns attached to the walls. The temple of Fortuna Virilis at Rome, (See Plate CLXIV.) is still smaller, being only 54 feet 8¼ inches in length from center to center of the angular columns, and 28 feet 8½ inches in width. It has only four columns in breadth of portico, and two in depth; and in the pronaos the two inner ones are omitted; and instead of the side walls being continued and finished with antæ as in Greece, there are columns attached to each of the external walls of the cells, which shew a semi-column both in front and flank; along the flanks and arriere end of the cell are semi attached columns. The columns are beautiful Roman Ionic, fluted and raised upon a pedestal, which, including two steps on the top of it, also surround the edifice, is 10 feet 5¼

Temple of Fortuna Virilis at Rome. Plate CLXIV.

inches high. The columns, including the base and capital, is 25 feet 4¼ inches high, and 2 feet 11 inches diameter. The entablature is 6 feet 8½ inches high, but has the parts ill proportioned; the architrave, 1 foot 4¾ inches, consists of a number of small plain mouldings; the frieze is only 1 foot 10¾ inches, and enriched; the cornice is 3 feet 5 inches, with a dentil band, and two other enriched members. The whole entablature has the appearance of a clumsy cornice, but being continued round the edifice without a break, preserves a great degree of simplicity. The plinth and dado of the pedestal are plain, but the face of the walls between the columns is rusticated.

Palmyra.

Of the other rectangular temples of the Romans, those of Palmyra and Balbec are not only the most extraordinary in point of extent, but are also in the highest style of decoration to which Roman architecture was carried. For a description of the general plan of the place, and of the various remains found within the precincts of Palmyra, we must refer to the valuable volume published by Messrs Dawkins and Wood in 1753, and for a specimen of the architecture, confine ourselves chiefly to an account of the temple of the Sun. The court in which the temple stood, measures over the walls, (by the scale upon the Plate,) 740 feet from north to south, and 720 from east to west. These inclosure walls consisted of a basement, or regular pedestal, about 16 feet in height; a plinth 2 feet 10 inches; and a regular order of Corinthian pilasters and entablatures; making, altogether, a height of 75 feet. The pilasters are 4 feet 6 inches diameter, and, exclusive of the entrance portico, there must have been 120 on the outside of the four walls, or sides of the rectangular court. From the surface of the outside ground to the level of the top of the pedestal (16 feet), there is a straight stair which extends 138 feet, which is the length of the portico, consisting of ten columns. This portico projects 49 feet before the face of the wall, rises to the same height as the pilasters, and has a pediment which rises more than one-fifth of the extent. The columns next the middle have been placed nearer to those next to them, in order to render the middle space wider than the other intercolumnations. The bases are attic; the architrave has many members; the frieze is an elliptical curve, and plain; the cornice has both dentils and enriched modillions; the other members, except some lions heads in the upper member, are plain. Immediately under the portico, the boundary wall is much decorated; the center doorway is 32 feet 6 inches high, and 15 feet 9 inches wide, with highly enriched architrave, trusses, and entablature. On each side is a door 16 feet 10 inches by 8 feet 10 inches, with plain architraves, and enriched soffit, trusses, frieze, and cornice. Over each of the side doors is a nich for a statue, having two small Corinthian columns on each side, also enriched frieze and cornice, and a shell in the domical head. On both sides of each of these doors are two heights of tabernacles, formed by pilasters and enriched frieze and cornice; the tops of these are flat, and the face of the pilasters plain. Over all these parts the general entablature of the portico passes, and although plain on the external face of the portico, it is here highly enriched. Though, exclusive of the projection of the pilasters, the inclosure wall measures only about six feet in thickness; yet, at the entrance under the portico, there is a solid of about 18 feet in thickness. The inner face of this very much resembles that which has just been described under the outer portico, only that the side doors, niches, and tabernacles, have pointed pediments. Round the inside of this court-wall, there are pilasters corresponding to those on the outside, so that there must have been 112; that is, eight fewer than on the outside, not counting the one quarter at each internal angle; between each of these pilasters there has been a tabernacle for a statue. Parallel with the inside of this western inclosure wall, is a row of columns, placed 48 feet 7 inches from the face of the pilasters, and at the distance of 8 feet 3 inches from each other, making 44 in number; besides two pilasters which distinguishes the extremities of the entrance portico, and upon which there is a pediment similar to that in the outside. The shafts of the columns are plain, but the entablature is highly and beautifully enriched, the ground of the frieze is flat, the foliage upon it has a very bold relief; against each shaft, (except those of the portico,) at about one third of its height, is a bracket, apparently to receive a statue. Alongst each of the other three sides of the court, were two rows of columns, similar to those already described, placed 19 feet from the face of the pilasters upon the wall, and the same from each other in that direction. Besides the larger clustered columns at the extremities of each row, and which were 12 in number, there were 51 in each row along the north and south sides, and 56 along the east and west sides, making altogether 226, and with the clustered columns 238, which, added to those along the western or entrance side, and inner portico, make 288 insulated pillars; in the circumference of this court, and along which there passed a highly enriched and delicately sculptured entablature, without a single break, excepting a very slight one to mark the extent of the entrance portico and its pediments.

Temple of the Sun.

Court.

Number of columns within the court.

Temple.

The temple itself stood 119 feet nearer to the eastern than the western colonnade, and about 22 feet nearer the south than the north. It was raised upon a platform, and this was ascended by steps which passed quite round it; the peristyle consisted of eight columns along each end, and 15 along each side, counting those at the angles twice; the length, over the columns, measures 190 feet, the breadth 103 feet; between the face of the pilasters upon the cell, and the inside of the columns of the peristyle, the distance is 22 feet 2 inches on the sides, and 22 feet 9 inches on each end; the height of the order, exclusive of the plinth upon which each column stands, (which is 1 foot 8 inches,) is 62 feet 8 inches; the shafts are fluted; the vases of the cups are now plain, but have marks shewing that metallic leaves and volutes have been fixed upon them; the architrave has one member enriched; the frieze is flat, and enriched by festoons of flowers held by female figures with wings; the cornice has dentils and modillions, and has every member except the corona enriched. On each side the principal entrance, which is on the west side of the edifice, there is a clustered column. The dimensions of the cell are, between the pilasters at the external angles, length 133 feet 4 inches, breadth 47 feet; between the pilasters, at each end, are two semi-ionic columns. The entrance door is 33 feet high and 15 wide; the architrave has one member enriched, the frieze and cornice are fully enriched; in the soffit is a bird like an eagle with wings extended. The windows, of which there are four on each side of the cell, are 8 feet 10 inches high, 4 feet 4 inches wide at the bottom, and 4 feet 2 inches at the top; they have architraves round the sides and top, on the outside pediments, and on the inside a flat cornice; they, on both sides, stand upon plain sills; the architraves are ten inches broad. Within the cell, at each end, are divisions like those of a modern chancel for an altar table, with a stair on one side and a small vestry on the other. Over the middle spaces, the soffits or cielings are enriched by sunk moulded pannelling of square octagonal and rhomboidal forms, each having a flower in the center. In the middle part of each soffit is a large circle; round one of them are the signs of the zodiac, and within it pentagonal compartments with busts, one evidently a Mercury, and another Apollo. Round the circle of the other soffit is a very rich fret work, and a large open flower in the center.

Long portico.

Next in consequence to this magnificent court and temple, is the ruin named the long portico, said to have been distinctly traced for a distance of 4000 feet; it commences at about 1200 feet to the north west of the temple; it is composed of four rows of columns, embracing a breadth of 82 feet; that is, the space between the middle row of columns being 37 feet, and on each side 16 feet; the diameter of the columns is 3 feet 8 inches; the intercolumn lengthwise 7 feet 2 inches. At the entrance to this portico is a gateway, consisting of three arched passages, the middle is 45 feet high, and 23 feet 6 inches wide; those on each side 22 feet high, and 11 feet 6 inches wide. The external and internal façades have Corinthian pilasters, and a pediment over the middle part; the pilasters are pannelled and enriched like those at Spalatro; the frieze is covered with acorns and small leaves. The height of this order, including a plinth of three feet, measures 57 feet 6 inches. The whole has the appearance of a fine triumphal arch. It does not stand at a right angle, but in an oblique position to the general direction of the portico.

We must deny ourselves the pleasure of entering upon the description of the other numerous temples and tombs of which vestiges were discovered, and proceed to give a short account of Balbec.

Balbec.

Approach to the temple of the Sun.

Balbec had been so completely destroyed, that the vestiges of three edifices only could be traced by Messrs Dawkins and Wood, as appears by their book, published in 1757. These consist of the Temple of the Sun, with its courts; another smaller temple immediately adjacent to it; and a singular circular temple, which stood about 400 feet to the south-east of the former. The great temple is first approached by a stair, 180 feet in length, rising 24 feet, to an oblong portico of the same length, and 40 feet in depth; and this portico has, at each end, an apartment 38 feet by 31 in the clear. The façade of this noble portico consists of 12 columns in the open part, and four pilasters at each end, standing against the before-mentioned apartments. The height of the order, which is Corinthian, is 52 feet; and, besides the general basement, which, as at Palmyra, forms a regular pedestal, there is here another about three feet six inches high. The diameter of the columns is four feet three inches at the bottom, and three feet nine inches at the top, and the intercolumn is 9 feet six inches, and eleven feet and eleven feet six inches. The bases are attic; the shafts are plain; the architrave has its upper member enriched; the frieze is flat and plain; the cornice has dentils and modillions, and has the upper member enriched; there is no break over the columns, and only a very small one at the pilasters. Over the order is an attic, or rather a pedestal with its plinth, dado, and cornice, altogether about ten feet in height. In this there is a small pilaster over each column and pilaster below, and upon the top of each there is a small square plinth. The whole height of this façade is 89 feet 6 inches. Under the porch, and in the apartments at each end, there is a succession of tabernacles in two heights; the upper ones having pediments over them, alternately circular and pointed; some having the level cornice interrupted by a shell, and others, a part of the raking cornice, leaving an opening in the middle part. From under this portico there are three passage door-ways; that in the middle is 34 feet high and 17 wide; those on each side 18 feet high and 10 feet wide. These doors are surrounded on the sides and top by very broad plain architraves. The friezes are all low, flat, and plain. The cornices have plain modillions. These entrances lead into an hexagonal court, two sides of which measure 110, and the other four 88 feet each; the breadth across being 146 feet. On five sides of this singular court, there are apartments, some 60, and others 63 feet long, and 22 feet in breadth. The back and end walls are filled with tabernacles. The sides next the courts are open, and each supported by four columns, 2 feet 9 inches diameter at the bottom, and 2 feet 5 inches at the top, and having intercolumns of 9 feet 6 inches, and 9 feet 8 inches, and 8 feet 7½ inches. Between these large apartments are others in the angles, of various shapes and dimensions. The sixth side forms an entrance into a large quadrangular court, measuring 374 × 368 feet; having along three of its sides oblong apartments, similar to those in the hexagonal court, from 57 to 80 feet in length, and 22 in breadth; and there are on two sides two semicircular recesses, 32 feet diameter, with five niches in each, and having two large columns in the open sides next the court: There are also, besides, eight rectangular apartments. The columns in this court are also 2 feet 9 inches diameter, with intercolumns from 8 feet 2 inches to 8 feet 4 inches. The orders in both courts appear to be the same in form and dimensions. They stand upon insulated pedestals, five feet in height. From the top of this, the order measures 33 feet 6 inches. The shafts are all plain. The architrave has the small beads and upper members enriched. The frieze is very low: The ground of it is flat, and is decorated by short festoons of flowers, suspended upon oxes' skulls, and small masks between them, all in bold relief. The cornice has dentils and modillions, and four other members enriched. Over the order is an attic, or pedestal, with small pilasters. The niches and tabernacles are finished similar to those in the portico, with pediments, pointed, circular, and broken; and there are besides, in the niches of the semicircular recesses, some pilasters with enriched pannels and capitals, with Corinthian bases, and Ionic angular volutes, and enriched ovolo resembling the Roman composite. When the whole of those courts were perfect, it is scarcely possible to conceive any thing in Roman architecture to have been more imposing.

Hexagonal court.

Quadrangular court.

Temple.

On a line with the extremity of this quadrangular court commences the peristyle of the temple; and the situation of the columns alone can be traced, of which, very fortunately, nine remain standing, and have their entablature perfect. There are ten in front, and nineteen on the sides, counting those at the angles twice. The extreme length over the columns measures 285 feet, the breadth 157. The diameter is 7 feet at the bottom, and 6 feet 5 inches at the top. The intercolumn is from 8 feet to 8 feet 10 inches. The middle, or entrance, opening at each end, is 13 feet 9 inches. The shafts consist of three pieces, joined by iron dowels above one foot diameter. The whole height of the order, including a plinth of four feet, is 87 feet. The bases are attic; the shafts are plain; the capitals are a chaste, beautiful Corinthian, with the members of the abacus quite plain; the architrave has the small beads, and two upper members, viz. an ovolo and cavetto, enriched; the frieze is very low, the ground plain, enriched by inverted trusses, with heads and masques over each, and festoons of flowers between them fastened to the masques by ribbons. Immediately over these lies a small, but very beautiful guilochi. A small fillet and bead divides this guilochi from the dentils; and they are only divided from the modillions by an enriched ovolo. Over the modillions projects the corona, having its face enriched by a double fret; and a small fillet and twisted ribbon divides this from a large semi recta, fully enriched with the acanthus leaf, Corinthian caulicola and masques. This seems to have been as rich an entablature as could be devised; and, in order to obtain richness, elegance has been sacrificed, by annihilating the deep Greek frieze, and converting the whole entablature into a massy cornice. There are no means of knowing, whether there has been any attic placed upon this entablature. The peristyle stood upon a basement of rough masonry, which it is thought was intended to be covered by a subbasement of large square stones, like those which now form one row of a terrace, along the north and west sides.

Terrace.

The length of these stones are from 31 to 35 feet; their breadth, besides the projection of the mouldings, is 10 feet 5 inches; and their thickness is 13 feet. Our travellers could not get to measure the height and breadth of the stones which composed the second row; but they found the length of three stones to make above 190 feet, viz. 63 feet 8 inches + 64 + 63 feet.

Smaller temple.

The next object is the smaller though more perfect temple; it stands upon lower ground than the former; its length over the columns measures 222 feet, and 114 feet 7 inches in breadth, so that even this smaller temple is longer than that of Minerva Parthenon in the Acropolis at Athens. It consists of 8 columns in front, and 15 on the sides; their diameter is 6 feet 5 inches, the intercolumns 8 feet 6 inches, and 8 feet 10½ inches, and 9 feet; that of the entrance is 11 feet 6 inches. Along the front are two rows of columns, besides other two in a line with the pilasters or antæ of the porch; along the sides and the other end there is one row only; these latter stand 9 feet 8½, and 9 feet 9 inches from the wall of the cell. The height of the order, including a plinth 1 foot 9 inches, upon which each column stands, is 76 feet 6 inches, being one and a half of the height of that of the Parthenon; therefore, in point of dimensions, even this edifice commands admiration. The entablature so exactly resembles that of the great temple, that it is unnecessary to repeat the description. The pedestal, upon which the order is elevated, measures 16 feet 4 inches in height, and is ascended by a stair in front 97 feet in length, to the level of the floor of the portico and temple.

Rich soffit of the peristyle.

The soffit, or lacunari, between the columns of the peristyle and wall of the cell, all round the temple, is fully enriched with sunk and moulded pannelling, they are in hexagonal, rhomboidal, and triangular forms; those which are rhomboidal contain busts of gods and heroes; the hexagonal contains entire figures of Leda, Ganymede, &c. all cut in marble in alto relievo.

Vestibule.

In the vestibule, the distance from the inner side of the second column in front to the entrance of the cell is 50 feet; the entrance door is 41 feet high, and 21 feet 4 inches wide; the side architraves are each of one piece, and those, as well as the frieze and flat cornice, are highly and delicately enriched; the architrave is 4 feet in breadth. On each side of this doorway there is a small staircase in the middle of the wall; and in the anterior angle of the cell, at this place, there are two small portions of columns clustered together.

Interior of the cell.

Along three fourths of the length of each side there is a colonnade, but instead of being insulated or attached to the wall, there is first square projections of two feet, placed at the distance of 6 feet 7 inches from each other, upon the face of which are attached semi-columns 4 feet 1 inch diameter, which, added to the former, makes a projection of 4 feet. This order stands upon a pedestal 11 feet high, the order itself measuring 49 feet, making the whole height from the floor to the springing of the arched roof 60 feet; the columns are fluted, and also the flat frieze; the small beads and upper members of the architrave are enriched, as is the whole of the cornice. It was judged that this part of the cell had been arched with ribs, corresponding to each pillar below, springing from the top of the entablature, and having their soffits enriched by guilochi, and the spaces between the ribs by sunk moulded square pannelling. Upon the face of the wall between the columns, there are arched recesses with enriched imposts and architraves; and over these, upon a moulded bracket, stands a regular entablature and pointed pediment. At three fourths the length of the cell, there is an ascent by steps to the height of 11 feet above the level of the floor of the body of the cell.

Thalamus.

Upon this level two semi-columns, each united to a pilaster, divide off this remaining space or thalamus, which is also ornamented by smaller pilasters, some of them in two heights with arched recesses or niches between them; there is a vaulted space under this raised floor, which also descends lower than the other or general floor.

Small circular temple.

The only other remaining edifice is the small circular temple 32 feet in diameter, filled with tabernacles, of which the peculiarity is that the entablature of the lower range is continued uninterrupted round the apartment, and that in the space between these in the upper range there stand single insulated columns; over the whole there passes a full entablature, and some of the stones, which composed the arched roof, still remain. The external order stands upon a pedestal 12 feet high; the order itself, including a plinth 1 foot 9 inches, is 39 feet high; the columns are 3 feet 1 inch diameter; the floor of the temple is upon a level with the level of the top of the pedestal, and is arrived at by means of a stair 19 feet in length; here 4 columns stand in a straight line, and a small segment is cut off the edge of the circle where the entrance doorway is placed; this forms a portico 50 feet in length. The remainder of the external circumference is encompassed by five reversed semicircles, each 24 feet diameter, and upon each of the points where they meet, which is 12 feet from the face of the wall, stands a column, between which the entablature, passing in the same circular manner as the basis, forms five semicircles. Opposite to each of these columns there is a pilaster upon the wall of the cell, and between these are enriched niches upon pedestals. Under the soffit of the general entablature, the upper part of the wall of the cell, between the before mentioned pilasters, is ornamented by festoons of flowers held up by boys. The whole edifice has a very light and striking effect.

General observations.

We have entered more into detail respecting the architecture of Palmyra and Balbec, because it is of singular magnificence at this extremity of the Roman empire; and having been faithfully measured and delineated, the different edifices afford accurate and perfect specimens of the style of the age in which they were constructed. It appears nearly certain, that the temple of the Sun at Balbec was built under the Roman emperor Ælius Antoninus Pius; and not only the other temple adjacent thereto, but the court and temple of the Sun at Palmyra, having so strict a resemblance in their general forms and sculptured ornaments, that we cannot help attributing the whole to the same people and period.

Our limits not admitting of more specimens of the Roman oblong temples, we must therefore proceed to

General observations. Pantheon at Rome.

those which were of a circular form, the most celebrated of which was the Pantheon at Rome. It has been generally attributed wholly to Agrippa; but from careful research, (see Maurice's *Indian Antiquities*,) Desgodetz asserts, that the body of the edifice is of much earlier origin; and that Agrippa only new modelled and embellished the inside, and added the magnificent portico. Desgodetz, indeed, gives a Plate, shewing the state of it previous to the time of Agrippa; but the Plate and description we shall insert in this work, represent the edifice in its improved condition. Desgodetz shews no architectural orders on the outside of the circular body of the edifice; whereas, Montfaucon gives an elevation from La Freri, in which there are, first, a high basement, then a regular Corinthian order, and upon that a regular composite order. We shall, however, follow Desgodetz. The dimensions are in French feet. See Plate CLXII.

Plate CLXII. Interior dimensions.

The body of the temple is circular. The inside diameter, taken on the ground floor, exclusive of the chapel recesses, is 133 feet; the thickness of the outer wall is 19 feet $1\frac{1}{2}$ inches; making the diameter of the outer circle 171 feet 3 inches. The height from the floor to the level of the springing of the dome is 65 feet $9\frac{3}{4}$ inches. The dome being semicircular, would, if complete, rise half the diameter. The opening at the top, however, takes something from this; but is compensated in the extension of the diameter, by the upper order receding from the vertical face of that below; so that the rise may be taken at half the diameter on the ground plan, viz. 66 feet 6 inches; making the whole height from the pavement to the top 132 feet $3\frac{3}{4}$ inches, or very nearly equal to the inside diameter.

Around the lower area there are seven chapels, in the thickness of the walls, each 27 feet wide, except that opposite the great entrance, which is 28 feet $9\frac{1}{2}$ inches wide. The three on each side have each two columns in the line of the entrance; two of them are square, and the middle one circular. That opposite the entrance is also circular, with a semicircular niche head. It has no columns in it, but one projecting without the general line of the walls, opposite to the pilasters on each side of the recess. The pilasters, on the side of the six chapel recesses, are square on their plan. The line which passes through their middle tends to the centre of the temple, as do the faces of the semi-pilasters in the inner angles of the four square chapel recesses. Between each of those chapels there is a tabernacle, each with two isolated columns and pilasters behind them, supporting alternately pointed and circular pediments. In the thickness of the wall there are void spaces, three tiers over each other, vaulted like niches. The lower ones were entered from the outside of the building; these have been made to lessen the quantity of the solid work, which would otherwise have been very great.

The Corinthian fluted columns and pilasters, which compose the lower interstices, stand immediately on the pavement. They are 3 feet 5 inches diameter, and 32 feet $5\frac{5}{12}$ inches high; the entablature is 7 feet $8\frac{7}{12}$ inches; making the whole order 40 feet 2 inches. The second order stands upon a high pedestal, and has a large cornice, but the pilasters, which are composite, are slender. In this attic there are 14 windows, but the temple is lighted chiefly by the great entrance, and the circular opening at the top of the dome, which is 37 feet in diameter. The dome has 28 vertical bands, which, besides the upper and lower margins, are crossed horizontally by four bands, which composes 28 × 5 = 140 square pannels, deeply recessed by degrees or square fillets. The entablature of the upper order passes quite round the edifice without any break; and the lower entablature is only interrupted at the great entrance, and chapel recess opposite to it.

Portico.

The portico is 98 feet $4\frac{1}{8}$ inches long, between the centre and centre of the extreme or angular columns of the front, and 41 feet $5\frac{1}{2}$ inches in breadth, from the centre of the angular column to the middle of the pilaster, or antæ of the solid part of the porch. There are eight columns in front, and three deep; but eight of the inner columns are omitted, viz. four opposite the entrance, and two opposite each niche on each side of the entrance. The angular column is 4 feet $8\frac{1}{2}$ inches, and the other 4 feet $6\frac{1}{2}$ inches diameter. The middle intercolumniation is 10 feet $4\frac{3}{4}$ inches, and the next 9 feet 5 inches. The height, including base and capital, is 19 modules $16\frac{1}{2}$ parts, which, taking the module from the angle column, makes the height equal to 46 feet, and the whole order 53 feet. The soffits of the pronaus are ornamented by pannelling of different forms. The great entrance is 36 feet $1\frac{1}{2}$ inch high, and 18 feet $4\frac{1}{2}$ inches wide. The jambs are each about $\frac{1}{8}$ of the width of the door, and each worked out of two pieces. The lintel is only one piece. In the pronaus on each side of the entrance is a large niche 17 feet 10 inches diameter. Besides the 16 isolated columns, there are three fluted pilasters on each side. Upon the square solid part of the porch, which projects from the circular body of the edifice, the diminution of the columns begins at the bottom. The bases, capitals, and entablature are of white marble. The shafts are of Egyptian granite, each of one piece. The pilasters, with their bases and capitals, are of white marble. The base round the outside of the building is of marble—all the rest of brick. The inside of the temple was incrusted with marble, as was the portico.

Outside.

The circular body of the edifice is encompassed round the outside by three cornices. The top of the first is at the height of 38 feet 10 inches from the level of the upper step of the portico; from the top of the first to the top of the second cornice is 29 feet; from the top of the second to the top of the third is 26 feet $6\frac{1}{4}$ inches; these taken together make 94 feet $4\frac{1}{4}$ inches. The cornices increase in size as they ascend; the upper one being 3 feet 6 inches thick, and 3 feet $1\frac{3}{4}$ inches projection: the two upper ones have modillions cut in stone; all the rest are of brick. Above the upper cornice is a retreat of 8 feet $11\frac{3}{4}$ inches, which slopes $18\frac{1}{2}$ inches. Over this retreat is a socle or pedestal, 6 feet 9 inches high, which has a small cornice. Upon this is a retreat of 4 feet 4 inches. The degrees, or plinths, or steps of the dome, which are six in number, have a slope; their edges are rounded, and they were covered with lead. The flat part at the top, which contains the opening, is 37 feet $5\frac{2}{3}$ inches. From the top of the upper cornice there is a small stair upon the outside of the dome leading to the top. On the outside of the circular body of the edifice, there appear arches in the brickwork in two tiers vertically over the chapel recesses, and other recesses in the walls. If the cornices, which encompass the edifice, are correctly marked by Desgodetz, there is neither recess nor projection, to admit of the Corinthian and composite orders, shewn in the elevation given by Montfaucon from La Freri.

Temple of Vesta at Tivoli. Plate CLXIII.

The small circular temple of Vesta at Tivoli. (see Plate CLXIII.) about five or six leagues from Rome, is built of Tiburtine stone, except the walls, which are of flint. A row of 18 Corinthian fluted columns surrounds the cell, from the wall of which they stand 5 feet $3\frac{1}{4}$ inches distant. They are 2 feet 4 inches diameter, and, including the bases and capitals, 21 feet 10 inches high. They stand upon a pedestal 7 feet 3⅓ inches high; and, from the pavement upon which it stands to the top of the entablature, the height is 33 feet. The inside diameter of the cell is 22 feet 2 inches, and the walls are 2 feet 1⅙ inch thick. The door and windows are narrower at top than bottom.

Temple of Vesta at Rome.

The temple of Vesta, at Rome, is nearly on the same model. It is surrounded by 20 Corinthian fluted columns, 2 feet 11 inches diameter. They also stand upon a pedestal, and at the distance of 7 feet 2 inches from the outside of the wall of the cell. Their height, including the base and capital, is 31 feet 9 inches. The inside diameter of the cell is 26 feet 2 inches. The wall is 2 feet 1½ inch. The dado of the pedestal is plain, but the outside of the wall of the cell is rusticated.

Temple of Faunus at Rome. PLATE CLXIII.

The temple of Faunus at Rome, (See Plate CLXIII.) built by the Emperor Claudius upon the Celian Mount, is likewise of a circular form, but is, in many respects, different from those we have just described. The interior body of the building, which rises to a very considerable height, is supported by low coupled Ionic columns, with an entablature; upon this a solid wall is carried up to rather more than equal to the height of the before mentioned order; at this height is placed a row of windows with semicircular tops; the space within this is divided equally by a column, from the capital of which rise two small semicircular arches, having for their other abutments the jambs of the general opening. The space or spandrel between these small arches and the circumscribing general arch, is pierced by a small circular opening, composing the same sort of windows which was afterwards named Saxon, Norman, Gothic. The general wall of the building is carried above the top of the windows about double their height, where it is finished by a cornice. This circular edifice has a division across it, which is carried to the height of the outer wall; the lower part of this division is formed by two isolated Corinthian columns, and two pilasters attached to the wall; the columns are so placed, that the middle space is wider than those on each side. These columns are about once and a half the height of the Ionic column which supported the outer circular wall. Immediately from the capitals, arches are turned which support the cross wall; in this wall are five large openings with semi-circular tops; viz. two over each of the side, and one over the middle arch. Without the before mentioned Ionic columns, and at a distance equal to about half the diameter of the space they inclosed, is a row of small Corinthian columns, about three-fourths of the height of the Ionic; these are connected by semicircular arches raised immediately upon the capitals; over these arches is a solid wall, which, including the arches, is about the same height as the order. These surrounded the whole central building, and formed a series of arcades similar to those afterwards introduced into the Christian churches.

Windows resemble Gothic.

Arches spring from the top of the capitals.

Besides those we have now described, there were many others, amongst the numerous temples at Rome, which were very magnificent, as the following dimensions will testify.

Examples.

	Diameter at bottom.		Height of column, including capital and base.

General observations.

Although the Roman architecture differed widely, in many respects, from that of the Greek specimens we have adduced and referred to, yet it seems probable, that, from the time of the Macedonian conquest, the Greek style had gradually degenerated, and that they had introduced this debased manner among the Romans, who generally employed Greek artists, as we learn from the following reply of the Emperor Trajan to a request of Pliny the consul, to have an architect sent him from Rome to examine a bath at Claudiopolis, a city in Asia, situated near the foot of Mount Taurus. "I entirely leave it to you to advise the Claudiopolitani as you shall think proper with relation to their bath, which they have placed, it seems, in a very improper situation. As there is no province that is not furnished with men of skill and ingenuity, you cannot possibly want architects; unless you think it the shortest way to procure them from Rome, when it is generally from Greece that they come to us." *Letter* xlix.

Whether the Romans removed old columns from the Greek structures for their works at Rome, or employed workmen to quarry and prepare them in Attica, we cannot distinctly make out from the following passage of Plutarch in his life of Publicola, where speaking of the temple of Jupiter Capitolinus, which was rebuilt, for the fourth time by Domitian, "The pillars are of Pentilic marble, and the thickness was in excellent proportion to their length, when we saw them at Athens; but when they were cut and polished anew at Rome, they gained not so much in the polish as they lost in proportion, for the beauty is injured by their appearing too slender for their height." But this might arise in some measure from Plutarch, who was a Greek, having been accustomed to admire the proportions of the Greek Doric in their magnificent temples.

From the foregoing specimens and descriptions of Roman temples, it will be evident, that they, in many respects, differed widely from those of the Greeks. The great Temple of Peace was nearly of a square form; in it there were circular recesses, and a number of arched windows in the outside walls; and the whole of the interior was covered by bold and lofty vaultings; those of the great middle aisle (77 feet 5 inches in width,) were groined arches. In the temple of Fortuna Virilis at Rome, the columns, excepting those of the entrance portico, were attached to, and only projected half their diameter from, the outside of the walls of the cell. In the Pantheon, instead of a square, a circular form was adopted, and the whole covered with one great spherical vault or dome. With the exception of the grand portico, it had all the ornaments, square recesses, and circular niches for the statues of the Gods, along the inside of the external walls, which left the whole interior space entirely clear. In the temples of Vesta at Rome and Tivoli, though circular, they were encompassed each with a row of Corinthian columns, and had their insides quite plain. In the circular temple of Faunus at Rome, the exterior of the main structure was encompassed by a lower one, consisting of an arcade whose arches sprung immediately from the top of Corinthian columns. The interior of the central building was divided by a straight wall, having in its lower part an arcade similar to that before mentioned. The upper windows of the central building were not only arched, but each was divided by a small column, from which rose small arches included under the main arch, and having a circular perforation over them; thus, in many respects, not only differing from the Greek, but affording the elements of Saxon and Gothic architecture.

Pliny's villa.

Plate CLXI.

Laurentinum.

We must rest satisfied with the foregoing specimens, selected from the numerous public buildings of the Romans, which were co-extensive with their empire, and shall next proceed to give some account of their private dwellings. The engraved specimen, Plate CLXI. is from Newton's *Vitruvius*, being considered the best authority; but we shall precede even that by the description which Pliny the consul gives of his winter residence at Laurentinum, which, being distinct and particular, will afford a perfect idea of the villa of a wealthy but not extravagant Roman nobleman; it was situated seventeen miles distant from Rome. "The landscape, on all sides, is extremely diversified; the prospect in some places being confined by woods, in others extending over large and beautiful meadows, where numberless flocks of sheep and herds of cattle, which the severity of the winter has driven from the mountains, fatten in the vernal warmth of this rich pasturage. My villa is large enough to afford all desirable accommodation, without being extensive. The porch before it is plain, but not mean, through which you enter a portico in the form of the letter D, which includes a small but agreeable area. This affords a very commodious retreat in bad weather, not only as it is inclosed with windows, but particularly as it is sheltered by an extraordinary projection of roof. From the middle of this portico you pass into an inward court extremely pleasant, and from thence into a handsome hall, which runs out towards the sea; so that when there is a south-west wind, it is gently washed with the waves, which spend themselves at the foot of it. On every side of this hall there are either folding doors, or windows equally large, by which means you have a view from the front and two sides, as it were of three different seas; from the back part you see the middle of the court, the portico, and area; and by another view you look through the portico into the porch, from whence the prospect is terminated by the woods and mountains which are seen at a distance. On the left hand side of this hall, somewhat farther from the sea, lies a large drawing room, and beyond that a second of smaller size, which has one window to the rising and another to the setting sun; this has likewise a prospect of the sea, but being at a greater distance, is less incommoded by it. The angle which the projection forms with this drawing room, retains and increases the warmth of the sun; and hither my family retreat in winter to perform their exercises. It is sheltered from all winds, except those which are generally attended with clouds, so that nothing can render this place useless, but what, at the same time, destroys fair weather. Contiguous to this is a room, forming the segment of a circle, the windows of which are so placed as to receive the sun the whole day; in the walls are contained a set of cases, which contain a collection of such authors whose works can never be read too often. From hence you pass into a bed-chamber through a passage, which, being boarded and suspended, as it were, over a stove which runs underneath, tempers the heat, which it receives and conveys to all parts of this room. The remainder of this side of the house is appropriated to the use of my slaves and freedmen; but most of the apartments, however, are neat enough to receive any of my friends. In the opposite wing is a room ornamented in a very elegant taste; next to which lies another room, which, though large for a parlour, makes but a moderate dining-room. It is exceeding warm, and enlightened, not only by the direct rays of the sun, but by their reflection from the sea. Beyond is a bed-chamber, together with its antichamber, the height of which renders it cool in summer: as its being sheltered on all sides from the winds, makes it warm in winter. To this apartment another of the same sort is joined by a common wall. From thence you enter into the grand and spacious cooling room belonging to the bath. From the opposite walls of which two round basons project, sufficiently large to swim in. Contiguous to this is the perfuming room, then the sweating room, and next to that the furnace, which conveys the heat to the baths. Adjoining are the two little bathing rooms, fitted up in an elegant rather than a costly manner. Annexed to this is a warm bath, of extraordinary workmanship, wherein one may swim, and have a prospect, at the same time, of the sea, together with the beautiful villas that stand interspersed upon the coast. At the other end is a second turret, in which is a room that receives the rising and setting sun. Behind this is a large repository, near to which is a gallery of curiosities, and underneath is a spacious dining-room, where the roaring of the sea, even in a storm, is heard but faintly. It looks upon the garden, and gestatio which surrounds the garden. The gestatio is encompassed with a box-tree hedge; and, where that is decayed, with rosemary; for the box, in those parts which are sheltered by the buildings, preserves the verdure perfectly well; but when, by an open situation, it lies exposed to the spray of the sea, though at a great distance, it withers. Between the garden and this gestatio runs a shady plantation of vines, the alley of which is so soft, that you may walk barefoot upon it without injury. The garden is chiefly planted with fig and mulberry trees, to which the soil is favourable, as it is averse from all others. In this place is a banqueting-room, which, though it stands remote from the sea, enjoys a prospect nothing inferior to that view. Two apartments run round the back part of it, the windows whereof look upon the entrance of the villa, and into a very pleasant kitchen garden. From hence an inclosed portico extends, which, by its great length, you might suppose erected for the use of the public. It has a range of windows on each side; but on that which looks towards the sea, they are double the number of those next the garden. When the weather is fine and serene, these are all thrown open; but, if it blows, those on the side the wind sets are shut, while the others remain inclosed without any inconvenience. Before this portico lies a terrace, perfumed with violets, and warmed by the reflection of the sun from the portico; which, as it retains the rays, so it keeps off the north-east wind; and it is as warm on this side as it is cool on the opposite. In the same manner it proves a defence against the south-west; and thus, in short, by means of its several sides, breaks the force of the winds, from what point soever they blow. These are some of its winter advantages. They are still more considerable in summer; for at that season it throws a shade upon the terrace during all the forenoon, as it defends the gestatio, and that part of the garden which lies contiguous to it, from the afternoon sun, and casts a greater or less shade, as the day either increases or decreases; but the portico itself is then the coolest when the sun is most scorching, that is, when its rays fall directly upon the roof. To these its benefits I must not forget to add, that, by setting open the windows, the western breezes have a free draught, and by that means the inclosed air is prevented from stagnating. On the upper end of the terrace and portico stands a detached building in the garden, which I call my favourite; and indeed it is particularly so, having erected it myself. It contains a very warm winter room, one side of which looks upon the terrace, the other has a view of the sea, and both lie exposed to the sun. Through the folding-doors you see the opposite chamber, and from the windows is a prospect of the inclosed portico. On that side next the sea, and opposite to the middle wall, stands a little elegant recess, which, by means of glass doors and a curtain, is either laid open to the adjoining room, or separated from it. It contains a couch and two chairs. As you lie upon this couch, from the feet you have a prospect of the sea; if you look behind, you see the neighbouring villas; and from the head, you have a view of the woods. These three views may be either seen distinctly from so many different windows in the room, or blended together in one confused prospect. Adjoining to this is a bed-chamber, which neither the voice of the servants, the murmuring of the sea, nor even the roaring of a tempest can reach; not lightning, nor day itself, can penetrate it, unless you open the windows. This profound tranquillity is occasioned by a passage which separates the wall of the chamber from that of the garden; and thus, by means of that intervening space, every noise is precluded. Annexed to this is a small stove-room, which, by opening a little window, warms the bed-chamber to the degree of heat required. Beyond this lies a chamber and antichamber, which enjoy the sun, though obliquely indeed, from the time it rises till the afternoon. When I retire to this garden apartment, I fancy myself a hundred miles from my own house, and take particular pleasure in it at the feast of the Saturnalia, when, by the licence of that season of festivity, every other part of my villa resounds with the mirth of my domestics; thus I neither interrupt their diversions, nor they my studies. Among the pleasures and conveniences of this situation, there is one disadvantage, and that is the want of a running stream; but this defect is in a great measure supplied by wells, or rather I should call them fountains, for they rise very near the surface."

To this we shall only add the general description of a villa, given by Vitruvius. "Those of the nobles who bear the honours of magistracy, and decide the affairs of the citizens, should have a princely vestibulum, lofty atrium, and ample peristylium, with groves, and extensive ambulatories, besides libraries and basilicas, decorated in a manner similar to the magnificence of public buildings, for in these places both public affairs and private causes are oftentimes determined." Again, "these rules also are applicable not only to the city houses, but likewise to those of the country, except that in those of the city the atrium is usually near the gate, whereas in the country, pseudo urbana, the peristylium is the first, and then the atrium, having a paved porticus around, looking to the palestra and ambulatories.' (Newton's *Vitruv.* b. vi. chap. 8.) See Plate CLXI. The names being inserted in each apartment, renders the use of them apparent by inspection.

Plate CLXI.

Revival of Roman Architecture, and its present state.

St Sophia at Constantinople.

Plate CLXXIII.

The church of St Sophia, erected at Constantinople, under the emperor Justinian, about the year 637, by the Greek architects Anthemius and Isodorus, forms an intermediate link between the ancient Roman architecture, and that revived about the latter end of the 15th, and beginning of the 16th century. In Plate CLXXIII, we have given a plan and section, from which it will be seen that the outlines of this structure resemble those of the temple of Peace at Rome. It has also, like it, the windows and other openings covered by semicircular arches; but instead of having the central part covered by a groined vault, it is surmounted by a spherical dome, in the manner of the Pantheon, but differing from that edifice in rising only about one-third of its chord-line, whereas that in the Pantheon rises one half. Where columns are used in the recesses from the middle aisle, they have base-mouldings, but no square plinths under them: the upper member of their capitals has some resemblance to the Ionic, the other part seems an awkward imitation of the vase of the Corinthian. The spaces between the columns are covered by arches springing immediately from the top of the caps, as in the temple of Faunus at Rome. The faces of the large square piers are covered with rectangular pannels. But the whole details are miserably inferior to either the Greek or ancient Roman architecture; and the frequent failures which took place in attempting to construct the dome, though under the direction of the best Greek architects of the age, are proofs of the degenerate state of the art at that period. The following short account of the manner in which the architects proceeded with this dome will, we have no doubt, be satisfactory to the reader, and prove instructive to the young architect. On the angles of a square of about 115 feet, four piers were erected, and carried up to nearly the same height, where arches were turned between them. The angular spaces between the archivolts of those arches were worked up so as gradually to form a complete circle at the level of the top of the arches. Upon this circle the dome was raised. The pressure of the eastern and western arches was resisted by walls, almost solid, running north and south, two in each direction, for about 90 feet. The small semi-dome which covered the circular recesses, were intended to resist the north and south arches; but they proved insufficient, for a few months only after the dome was completed, it gave way towards the east, fell down, and carried with it the semi-dome on that side. The architect then added to the eastern piers, by filling up some vacuities, and reconstructed the dome. But the resistance at the east end was still insufficient, for before it was completed it fell a second time. He then constructed strong buttresses against the wall of a square cloister, which surrounded the central building, and from thence carried arched buttresses over the interval to the main building, and a third time raised the dome, taking care to diminish the thickness, and for lightness to make use of pumice-stone. But after all, he found it necessary to fill up the arches on the north and south sides with others of smaller dimensions.

The early Christian churches were built with a great number of columns, because those were found ready worked among the ruins of ancient edifices. When this mode of supply failed, towards the end of the 10th century, the clumsy workmen were obliged to substitute massy piers and arcades.

If we were to follow the practice of architecture as it succeeded in point of time, we ought here to introduce and describe specimens of the Gothic school; but for simplicity and distinctness, we prefer following the Roman to its revival and present state, reserving the Gothic to the latter end of this article.

Component parts of an edifice.

Previous to producing specimens of the different variations of style which have taken place in the course of the last 400 years, we shall endeavour to discuss the component parts of a building; which being generally applicable, we are unavoidably led to consider frequently as connected both with ancient and modern practice.

Foundations.

FOUNDATIONS. This term is applied to the excavation made in the ground for the base of a building. The trenches should be sunk till they arrive at firm soil or solid rock; and in large buildings, the ground should be further proved by digging pits, or boring to a considerable depth. If the ground be rather soft or loose, but tolerably firm, pieces of oak, termed sleepers, are laid across the trench, about two feet distant from each other, their lengths being about two feet more than the bottom of the intended wall, and the spaces between them is filled with dry stone rubbish or iron cinders well rammed. Over these sleepers, planks are laid to a breadth somewhat exceeding that of the masonry, and are spiked to the sleepers; and this operation must be extended to all the walls, external and internal, that the whole edifice may have an equal bearing. If the ground be very soft and loose, wooden piles must be driven to secure the planking. They should be of a sufficient length to reach the solid ground, and be driven as close together as practicable. Their thickness should vary from being about one-sixth of their length in short piles, to one-twelfth in long ones. Where the ground is generally firm, but having some soft spaces, arches may be turned over the latter. When the superstructure is to stand on narrow piers, inverted arches should be turned between; if the ground under these is loose, piles and planking must likewise be used. When the foundations are upon slanting ground, the trenches must have their bottoms cut in rectangular steps. Forced earth is unfit for foundations, and can scarcely be rendered fit by any precaution short of making a sufficient platform, connected with the original unmoved ground.

Foundations of walls.

Besides the foregoing application of the term *Foundation*, it also indicates the substructure, or bottom of a wall, which consists of one or more offsets or steps on each side of its perpendicular faces. These are denominated footings. The breadth of this substructure must be proportioned to the weight of the superstructure, and the nature of the ground. Where the texture of the soil appears to be tolerably equal and firm, and the materials of similar specific gravity, the breadth will be as the area of the vertical section passing through the line in which it is measured. For example, suppose a wall 40 feet high and 2 feet thick to have a sufficient foundation at the breadth of 3 feet, what should the breadth of the foundation be, when the wall is 60 feet high and $2\frac{1}{2}$ feet thick? By taking the proportion $40 \times 2 : 3 :: 60 \times 2\frac{1}{2}$, we shall have $5\frac{5}{8}$ feet. In stone walls, the least breadth added to that of the superstructure, is one foot. In damp situations, charcoal, sand, tarred paper, and Parker's British cement, may all be used with advantage.

Of walls.

WALLS IN GENERAL.—A wall should be able to resist a given force, acting upon it either with uniform pressure over the whole surface, or pressing partially upon certain portions. It should be capable of sustaining the pressure of vaults or roof acting along a continued abutment; or upon points, as groin vaulting; also the power of the wind acting uniformly upon the whole surface; and all these are to be ascertained by calculations which the properly qualified architect will be capable of making. He may also be assisted by referring to the theory of arches in the article BRIDGE.

Different sorts.

There are many sorts of walls: We shall first insert the substance of what has been said on the subject by Vitruvius and Palladio, and then explain the modes practised in the present day.

Plate CLXXXIX. Fig. 1.

The wall which Vitruvius names *uncertain*, is one where the stones are laid in their natural shape and dimensions, so that the size and figure of the courses are various, as at A, (see Plate CLXXXIX. Fig. 1.) Perrault calls those *inserted*, when the stones are of a determined size, and placed in a regular order like brick-work. In this sort of work the stones should be longer and shorter alternately, or their position varied, so as to break joint, tie together, and render the whole firm and close. The Greeks made their walls frequently in the manner of brick walls, with a hard stone, having the outer face of a square form, that is, of equal depth and breadth, such as B, Fig. 2; or with stones of irregular size, as C, Fig. 3. The third sort were termed *involved*, as D, Fig. 1, where the stones were even in the front, but laid irregularly. Walls were termed *cramped* when the interior was composed of rubble, or broken or pounded cement, and the outsides of squared stones tied together by iron, as at E, Fig. 4; or where the squared outside stones were occasionally connected by long stones that went through the whole thickness of the wall, as at F, Fig. 4; and sometimes these stones went only about two thirds of the thickness, having a stone overlapping it from the other side in the next course. The term *network*, or *reticulated*, was applied to work, where the stones were square in their outer faces, but laid in courses inclining to the horizon at an angle of 45°, as G, Fig. 5. This mode was much practised at Rome, but is not calculated to afford stability.

Fig. 2.
Fig. 3.
Fig. 4.
Fig. 5.

The precepts of Palladio are as follow: Net or reticulated works (A, Fig. 6.) he condemns as being unstable; but if it is to be used, he proposes to construct buttresses at the angles BB, and place transversely or longwise six courses of stones or bricks laid horizontally at the bottom CC, and in the middle three, as DD, wherever the net or reticulated work is raised six feet.

Fig. 6.

Brickwork, in walls of considerable magnitude, he directs to be constructed as at EE, Fig. 7, the rubbish lying concealed in the middle as at FF. In the bottom to have six courses of bricks of a larger size than ordinary, then to build up about three feet in height with the common-sized bricks, and upon these to bind the wall again with three courses of the larger bricks. Specimens of this mode are found in the Pantheon and baths of Dioclesian at Rome.

Fig. 7.

A third sort of walls is composed of rough pebbles out of a river, or taken from a rock, and laid irregularly in cement, as at I, Fig. 8. This should be bound by three courses of bricks at every two feet in height, as K. This kind of work is seen in the walls of Turin in Piedmont.

Fig. 8.

The fourth sort is termed *uncertain*, as L, Fig. 9; a specimen of which remains at Preneste, twenty miles from Rome.

Fig. 9.

The fifth mode is composed with squared stones, as at M, Fig. 10. It is named *pseudisodomum*, and is to be seen in the temple of Augustus at Rome.

Fig. 10.

The sixth, as at Sirmion upon the lake of Garda. They are formed by making two sides of stakes and planks, as N, Fig. 11, between which stones and mortar are thrown in promiscuously; when these have set or con-

Fig. 11.

solidated, the wooden frames are removed, and the sides of the wall appears as at O. This is termed *formaceous*.

Plate CLXXXIX. Fig. 12.

A seventh sort of work is seen in the ancient walls of Naples, where two outside walls are built of squared stones laid in regular courses, PP, Fig. 12, bound together by transverse or cross walls at certain distances, as QQ, and having the remaining spaces between these walls filled up with stones and earth.

General remarks.

The ancients bestowed great pains upon forming the beds and joints of the stones; they were frequently so fine as to escape the eye. They usually worked only at first the bed and joints, and having set the stones in this state, afterwards polished the faces.

Palladio directs, that as the wall rises above the ground, its thickness should diminish in the manner of a pyramid; that the inside face of the wall should be in a perpendicular line; that the thickness of the podium or foot of the wall, be half that of the foundation; in the middle of the wall, or front band, the thickness be diminished half a brick; at the top, or crown of the building, another half brick to be taken away; and, that some sculpture, or bas relief, should conceal outwardly the gradual diminution. That great attention should be paid to render the angles as firm as possible by means of long and hard stones; and that the openings, windows, &c. be removed, at least to the distance of their own breadth from the angles.

Modern house-building.

In modern house building, the bedding joints of the squared stones or bricks have always a horizontal position. In piers, quays, and bridges, the bedding joints are generally laid at a right angle with the latter of the outside faces; and these latter are sometimes worked in the reticulated manner, that is, the courses are laid at an angle of 45° with the horizon. But this subject will be more fully discussed under the article MASONRY.

Footings.

The footings in the foundations of stone walls should be composed of large square stones, all of the same course, being of an equal thickness. If the foundations are made to taper much, the superstructure will depend on the back parts of the lowermost stones, and unless these are very truly worked and laid, it will therefore be liable to give way. Where the direction of a wall is up the face of steep ground, cut into steps, the footings must be bedded with great care; and all the upright joints of an upper footing stone, should break joint, or fall upon the middle of the stones below. In laying the foundations of thin walls, where stones of proper size can be had, each course of the footing should consist of stones reaching the entire thickness of the walls, with the proper projections. But in thicker walls, when only a part of the stones can be had of sufficient length, then every alternate stone may be laid quite across the wall; the interval consisting of two stones in breadth after the manner of Flemish bond in brickwork. If even these bond stones cannot be procured, then every alternate stone may be in length two thirds of the thickness on one side the wall, and on the other side a stone of one third of the same breadth may be placed, and the order reversed in the next course, which will form a sufficiently strong bond. In broader foundations, where stones cannot be procured equal to two thirds of the breadth, they may be built with the joints of the upper course of each footing resting nearly on the middle of the stones in the course below it.

Disposition of materials.

ubble wall.

When the superstructure of a wall consists of unhewn stone laid in mortar, it is called a *Rubble Wall*, which may be either *coursed* or *uncoursed*; of these the latter is very common in ordinary buildings. The greater part of the stones are used as they come from the quarry; some have a slight hammer dressing. This sort of wall is very inconvenient for receiving bond timbers; but if *bond timbers* be preferred to *plugging*, the backing must be levelled in every height where the bond timbers are required. When the stones are very small, and of irregular shape, it will add to their stability to work in slender laths or old hoop iron; and care must be taken to dispose the longest sort of the stones so as to create the greatest possible bond; and the work must be carried very regularly up round every wall of the building, and with not too much rapidity, in order that it may have time to indurate or set, to a certain degree of firmness before a great weight comes upon it; and on no account should thin stones be set on edge, which thoughtless and unprincipled workmen are but too much inclined to, either from haste, or for the purpose of making a smooth out-side facing.

Plugging.

No thin stones to be set on edge.

Coursed rubble.

Coursed rubble, where proper stones can be obtained, is much preferable to the other, and is more favourable to the disposition of bond timbers. The courses are of various thicknesses, adjusted by means of a guage or sizing-rule; and the stones are either hammered, dressed, or axed.

Ashler work.

Walls faced with squared stones, and backed with rubble or brick, are called *ashler work*, and the stones themselves are called ashlers. The average size of each ashler is from 24 to 36 inches in length horizontally, 8 to 12 inches in breadth or depth, and 10 to 16 inches in height. The best figure for the stones of an ashler facing, is that of a truncated wedge, that is, thinner at one end than the other in the thickness of the wall, so that those in one course may form in their back parts indentations like the teeth of a saw, the next course having its indentations varied from that below it; the whole is therefore toothed or united with the rubble backing, much more effectually than if the backs of the ashlers were parallel with the face. Bond stones should be introduced in every course of ashler facing: they should be in quantity equal to one-sixth of the face of the wall, and of a length to reach at least one foot into the back, but the more the better. every bond stone should, if possible, be placed in the middle between those in the course below. When the jambs of piers are coursed with ashler, or when the jambs are of one entire height, every alternate stone next the aperture in the former case, and next to the jambs in the latter, should bond through the wall; and every other stone should be placed lengthwise, in each return of an angle, not less than the average length of an ashler. Bond stones should have no taper in their beds, nor should their ends, or the ends of the return stones, be ever less than 12 inches. *Closers* should never be admitted, unless they bond at least two-thirds of the thickness of the wall. All upright joints should be square or at a right angle with the face for about two inches back, after which they may widen a little towards the back. The upper and lower beds of every stone should be quite level or parallel to each other for their whole breadth. All the joints, for the distance of about one inch from the face, should be cemented with fine mortar, or with a mixture of oil-putty and white lead; the former is practised at Edinburgh, the latter at Glasgow; at the latter place the joints of the polished ashler work are uncommonly fine and accurate. Parker's British cement will probably supersede both the former. The remainder of the ashler, and all the rubble, should be laid in good lime mortar; that for the rubble should be made with coarser sand. All the stones should be laid in their natural beds. Wall plates should always be placed on a number of bond stones, to which they may be either joggled or fixed by

Vaults and domes.

VAULTS, DOMES, or GROINS.—A vault is an interior roof, rising in a concave direction from the walls on which it rests, either in a continued arch from side to side,—in which case the section is semicircular, or a section of a circle less than a semicircle,—or else meeting the vertex in a point, or line, as when the section is Gothic.

The concavity, or interior surface of the vault, is called the *intrados;* which, in simple vaulting, generally consists of the portion of the surface of a cylinder, cylindroid, or sphere, never exceeding half the solid; while the springing lines, from which the vault rises, and by which the walls are terminated, are generally straight, and parallel to the axis.

Denominations.

Vaults having a horizontal straight axis, are called *straight vaults;* and those with their axes horizontal are termed *horizontal vaults.*

The exterior, or convex curve of the superior surface of an arch, is called the *extrados.*

The vertical sections of the intradosses of vaults may be formed in curves of an infinite variety; but the most elegant are circular or elliptic, and have been adopted among the Romans, by some of our ancestors of the middle ages, and by the nations of modern Europe. To these, therefore, we shall at present confine our observations.

A cylindrical, or cradle vault, consists of a plain arch; the figure of whose extrados is a portion of a cylindrical surface, terminating on the top of the walls which support it, in a horizontal plane parallel to the axis of the cylinder.

A cylindroidal vault consists also of a plain arch, the figure of whose extrados springs from a horizontal plane, but its section perpendicular to those lines is every where a semiellipsis, equal and similar throughout, having its base that of either axis; otherwise, it is sometimes the segment of an ellipsis less than a semiellipsis, having an ordinate parallel to the axis for its base.

A vault, rising from a circular, elliptical, or polygonal plan, with a concavity within and a convexity without, so that all horizontal sections of the intrados may be of similar figures, having their centres in the same vertical line, or common axis, is called a *dome.*

Various names are given to domes, according to the figure of their plan, as polygonal, circular, or elliptic. Circular domes may be either spherical, spheroidal, ellipsoidal, hyperbolical, parabolical, &c. Such as rise higher than the radius of the base are called *surmounted domes,* and such as are below this altitude are termed *diminished,* or *surbased domes.* If a dome be a portion of a sphere, that is, if its base be a circle, and its vertical section through the centre of its base the segment of a circle, it is called a cupola. A spherical dome, or cupola, may be intersected by a cylindric vaulting in any direction; and the intersection will always be circular, provided the axis of the cylinder tend to the centre of the sphere, because every section of a sphere made by a plane is a circle, as is also every section of a right cylinder perpendicular to the axis. Suppose, therefore, the sphere to be cut by a plane forming a section equal to that of the cylinder, and the two sections applied together, the right line drawn from the centre of the circle, which is the section of the sphere, to the centre of such sphere, will be perpendicular to the plane of this section; and, since the axis of the cylinder is also perpendicular to the same plane, it will be in the same right line with the remainder of the radius of the sphere. From this we deduce, that, when the axis of a cylindrical vaulting is horizontal, and tends to that of a spherical vault, their intersection must be in the circumference of a circle, whose plane will be perpendicular to the horizon; and hence those beautiful sphero-cylindrical groins, so greatly and justly admired in our principal buildings.

Upon this principle, any building that has a polygonal base may be made to terminate a circle, and sustain a cupola, or cylindric wall; for, if the tops of the side walls of the polygon be brought to a level, and equal segments of circles, whether semicircles or less portions, be raised on the top, meeting in the lines of intersection of the sides of the polygon, and if the angular spaces between the circular-headed walls be made good to the level of the summit of the arches, so as to coincide with the circumference of a great circle of the sphere, they will terminate in a ring at the level of the summit of the arches, and be portions of the sphere, called by our workmen *spandrels,* and by the French *pendentives.* On the ring so formed, a cornice is usually laid, on which the cylindric wall or dome is raised.

Spandrels or penden tives.

The plans of apartments intended to be covered with cupolas, are, in general, either square or octangular. The pendentives are likewise commonly equal in number to the angles of the walls; but this is not essential, because, in polygonal plans, arches may be thrown across the angles, to double the number of the sides of the polygon, still preserving the equal sides. Over the middle of the walls, equal and similar arches may be built, that shall touch those across the angles at the bottom, and have their tops in the same level: Or, instead of walls, piers may be carried to an adequate height upon each angle of the polygon, and return upon either side of it. Archivolts may then be turned over every two adjacent piers, and the spandrels be filled in to the level of the summits of the arches or archivolts, as before, and the termination will be a circle on the inside, as already stated.

No antien penden- tives.

There do not appear any instances among the Roman buildings, of pendentives or spandrels being supported by four pillars, or by quadrangular or polygonal walls, and which support themselves on a spherical dome or a cylindrical wall. Pendentives rising from pillars, and surmounted with a dome, were originally introduced in the celebrated church of St Sophia at Constantinople. St Paul's, and St Stephen's, Walbrook, London, are beautiful specimens of this sort.

Groins de scribed.

When two or more plain vaults penetrate or intersect each other, with their summits in the same horizontal plane or level, the figure of the intrados, formed by the several branches of the vaults, is called a *groin:* In other words, a groin is a vault in which two geometrical solids may be transversely applied, one after another, so that a portion of the groin will have been in contact with the first solid, and the remainder with the second when the first is removed, and that the summit of the one may intersect that of the other. This definition will be found almost universal, as it applies not only to plain vaults intersecting each other, but also to such as are annular, or in the form of semi-cylindric rings, intersected by cylindric or cylindroidal plain vaults, whose axes tend to that of the annuli; but it does not include the species used in the chapel of Henry VII. at Westminster, and in King's College chapel at Cambridge, where, instead of the horizontal sections of the curved surfaces presenting exterior right angles, as is generally the case, they present convex arches of circles.

A property common to every kind of groins, is, that the several branches intersect and form arches of equal height upon each inclosing wall, the perpendicular surface of which is continued on both sides, till intercepted by the intrados of the arches; consequently, the upright of each wall is equal in height to that of the common apex of the arches. This forms a striking and characteristic difference between domes and groins: the latter is a branched vault, terminating in each branch against the inclosing wall; whereas the former is a vault without branches, having its curves springing from all points of the wall or walls around the bottom of its circumference, whether upon a polygonal, circular, or elliptical plan. Another property of the dome is, that all its horizontal sections are similar figures, whether made by the exterior or interior surface.

Groins are variously denominated, according to the surfaces of the geometrical bodies which form the simple vault, viz.

Rectangular groin.

When the axes of the simple vaults are in two vertical planes, crossing at right angles to each other, they form a *rectangular groin*.

When three or more simple vaults of one common height pierce each other, and form a complex vault, in such a manner that if the surfaces of the several solids of which each is formed were respectively applied, one at a time, to succeeding portions of the surface of the complex vault, each portion of the complex vault would come in contact with certain corresponding portions of the surface of each of the solids: the complex surface thus generated is called a *multangular groin*.

Multangular groin.

When the several axes of the simple vaults form equal angles around the same point, and when each of the vaults are of the same width, the surface of the solid is called an *equiangular* groin.

Equiangular groin.

Equilateral groin.

When the breadths of the cross vaults, or openings of a groined vault are equal, the groin is said to be *equilateral*.

The species of every groin, formed by the intersection of two vaults of unequal width, is denoted by two preceding words; the first ending in *o*, indicates the simple vault of the greater width, and the second terminating with *ic*, denotes the simple vault of the less width.

Thus, a cylindro-cylindric groin, is a groin in which the cylindric portion is wider than the cylindroid. In this species of groin, the section of the cylindroidic part has its lesser axis horizontally posited.

A cylindroido-cylindric groin is one which has the greater axis of the cylindroidic part horizontally posited.

When the two portions of a groin are of equal width, the groin is either cylindric or cylindroidic, accordingly as the portions are both cylinders or both cylindroids.

When one vault pierces another of less height, the angle formed at the intersection is called an arch, and its species is indicated by the two preceding words, as in groins; that ending in *o*, indicates the simple vault of the greater height, and the other ending in *ic*, denominates that of the lesser height.

A cylindro-cylindric arch, is an arch made of two cylindric portions; but the portion indicated by the word ending in *o*, is higher than the portion ending in *ic*.

A sphero-cylindric arch is that in which the spheric portion surmounts the cylindric portion, or that the principal or master vault is a sphere, and the other which perforates it a cylinder.

A cylindro-spheric arch is one in which the higher arch is a portion of a cylinder, and the other a portion of a sphere, as must be the case with a spherical headed niche in a cylindric wall, or in a cylindric vault.

Greeks did not make vaults, &c.

It does not appear that the Greeks made use of vaults or arches prior to the Roman conquest; but from that period they employed not only plain vaults with cylindrical intradosses, but also quadrilateral equal-pitched groined vaults, with cylindrical or cylindroidal intradosses, or a mixture of both, as may be observed over the passages of the theatres and gymnasia.

Dome, Roman.

The dome was invented by the Romans or Etrurians. The Pantheon, which is generally reputed to have been built by Agrippa, son in-law to Augustus, (though some writers maintain that he only added the portico), is one of the earliest remaining structures with arches: it consists of a hemispherical cavity enriched with coffers, and terminates upwards in an aperture called the *eye of the dome*. The exterior side rises from degrees or steps, placed in a sloping direction, and forming nearly a tangent to the several internal groins of the steps, presenting to the eye a truncated segment of a sphere, much less than a hemisphere. This forms the general character of the Roman dome.

Domes were of very frequent use among the Romans, as may be deduced from their groins, and the remains of their ancient edifices. But ancient Greece does not furnish a single example of a dome, if we except that which covers the monument of Lysicrates, but which being only of a single stone, may rather be deemed a lintel than a built dome.

Vitruvius observes, (Book iii. chap. 8.) that the floors of temples were frequently supported by vaults, and (book v. chap. 1.) that the roofs of basilicas were vaulted in the tortoise form, which he distinguished by the term *testudo*. This mode of vaulting is very flat, and has four curved sides springing from the four walls, approaching nearly to the form of a flat dome upon a rectangular plan.

From the remains of Roman buildings we also observe that their ceilings were vaulted over their apartments, as may be seen in the chapels of the temple of Peace, and the side apartments of Dioclesian's baths, which are furnished with vaults having cylindrical intradosses; while the great rectangular apartments, in both these edifices, are vaulted with groins. Nor is it a little remarkable that these groins are not formed by the intradosses of the vaults of the chapel, whose summits rise but a small distance above the springing of the middle groins. The piers between the chapels also have small arcades, the summits of which are considerably below the cylindrical intradosses of the side vaults; a mode to be discovered in many other buildings.

Annular vaults. Temple of Bacchus.

The Romans used annular vaults, as in the temple of Bacchus, where, as in the temple of Peace and the baths of Dioclesian, the summits of the arcades, supporting the cylindric wall and dome of the central apartment, do not intersect the annular intrados, but the convex side of the cylindric wall which supports it, consequently they do not form groins.

General observations.

The intradosses of the Roman domes, as we have already hinted, are of a semicircular section, as in the Pantheon, and the temple of Bacchus at Rome, the temple of Jupiter, and the vestibule of the palace of Dioclesian at Spalatro; while the vertical section of the extrados through the axis, exhibits a much less segment, as may be seen in the first and last of the examples quoted. The latter observation, however, only applies to edifices built prior to the reign of the emperor Justinian; after which period, from the completion of the dome of St.

Sophia at Constantinople, to the finishing of St Paul's cathedral at London, the domes are all of the surmounted kind, and approach, in a certain degree, to the proportions of spires or towers, so much affected in the middle ages. Since the labours and taste of Mr Stewart and others have revived the legitimate Grecian architecture, the contour of the ancient Roman dome has been also restored, especially in cases where the structure is ornamented with any of the orders.

In the interior of the large towers of our Gothic cathedrals, over the intersections of the cross, we find domes, rising from a square base, generally pierced with two windows over each wall, and forming beautiful groins, by their intersection with the interior domic ceiling.

Equilibrium of domes.

Though the equilibrium and pressure of domes are very different from those of ordinary arches, yet they have some common properties, as will appear from the following comparison: If, in their cylindrical or cylindroidal vaulting of uniform thickness, the tangent to the arch at the bottom be perpendicular to the horizon, the vault cannot stand; neither can it be built with a concave contour in the whole, or in any part; and to make the arch in equilibrium, whether its section be circular or elliptical, supposing the intrados to be given, the extremes must be loaded vastly high, between the extrados of the curve, which runs upward, and the tangent to the arch, which is an asymptote, rising vertically from each foot or extreme of the arch. In like manner, in thin domical vaulting of equal thickness, if the curved surface rise perpendicular from the base, the bottom will burst, let the contour be as it may.

Notwithstanding this agreement, dome vaulting differs in other particulars very essentially from the common sort; for instance, to bring the figure of a dome into proper equilibrium, after the convexity has been carried to its full extent of equilibrium around, and equidistant from the summit on the exterior, the curvature may alter into a concavity; for, since the interior circumference of the courses is less than that of the exterior, the stones cannot fall inwardly, whatever be the outward pressure, unless they be squeezed into a less compass, which is supposed impossible; consequently, they must be crushed to powder before such a vault can give way. For the same reason, a vault may be constructed, that shall be convex within, and concave outwardly, and yet be sufficiently firm. The strongest form, however, of a circular vault, intended to bear a load at the top, is that of a truncated cone, similar to Sir Christopher Wren's contrivance for supporting the stone lanthorn and exterior dome of St Paul's. In this kind of vault, the pressure is communicated in the sloping right line of the sides of the cone perpendicular to the joints, consequently the conic sides have no tendency to bend to one side more than to the other, unless it be from the gravity of the materials tending towards the axis, which is counteracted by the abutting vertical joints: A form so strong, as to be adequate to sustain or repel any force acting on its summit that we can possibly conceive.

In dome vaulting, on the contrary, the contour being convex, there is a certain load, which, if laid on the apex of the dome, must cause it to burst outwardly. The power of this load will be greater or less, according to the approximation of the contour towards, or its recession from, the chords of the arches of the two sides, or to a conic vaulting on the same base, carried up to the same altitude, and ending in the same circular course. In exemplification of this, if we begin at the keystone, and proceed downwards, from course to course, supposing a horizontal line to be a tangent at the vertex, we shall discover, that every successive coursing-joint may be made to slope so much, and, consequently, the pressure of the archstones of any course towards the axis may be so great, as to be more than sufficient to resist the weight of all the part above; hence it is evident, that a certain degree of curvature may be given to the contour, which will be just sufficient to prevent the stones, in any succeeding course, from being forced outwardly.

A circular vault, thus balanced, is what is called an *equilibrated dome*; but it is the weakest of all vaults, between that of its own contour, and that of a cone upon the same base, rising to the same height, and ending in a key-stone, or finished with an equal circular course.

Boldest contour.

From these data we may conclude, that the equilibrated dome has the boldest contour, but is only the limit of an indefinite number of inscribed circular vaults, all stronger than itself.

In other respects circular vaulting differs from the straight, in being built with courses in circular rings; so that the stones in each course being of equal length, and pressing equally towards the axis, cannot slide inwardly. Hence circular vaults may be left open at the top, and even the equilibrated dome may carry a lantern of equal gravity with the part that would have been necessary to complete the whole. But domes of a more flat contour may carry more, according as they approach nearer to a cone, as already remarked; and those circular vaults that are either straight or concave on the sides, may be loaded without limit, and can never fail till the materials are crushed, provided they be hooped at the bottom. For a more complete investigation of this important subject, see DOME.

Arches.

We have already observed, that, from the earliest periods of Roman architecture, ARCHES have been of importance, and have been extensively used in the construction of most sorts of edifices; but, as their nature and principles have been treated of at some length under the term BRIDGE, we shall at present only observe, that they are introduced to cover openings to which lintels are inadequate, as drains and inverted arches in foundations, in vaulting over cellars, halls, and passages; also over doors, windows, and recesses. They are, indeed, become so generally useful, and are capable of so nice and accurate adjustment, that we cannot too earnestly press upon the young architect, the propriety of rendering their principles and practice perfectly familiar to his mind.

Balusters.

BALUSTERS are sometimes of real use, as in stairs, windows, terraces, and on the sides of passages open on one or both sides. At other times they are merely ornamental, as when terminating the upper part of the front of a building, as a screen to conceal the whole or part of a roof, or as a finish to insulated triumphal arches or gateways. They consist of short pillars, of a peculiar outline, standing upon a socle or plinth, and covered with a small cornice. No remains of balusters have been found in any ancient buildings. In the theatres and amphitheatres of the Romans, the pedestals of the upper orders were always continued through the arcades, and served as parapets. The lower seats, next to the arena in the amphitheatres, and those next the orchestra in the theatres, were guarded by a parapet called the podium. The top of the monument of Lysicrates at Athens is finished with a sort of parapet or ledge, composed of honey suckles, solid behind, and open between every pier. Each plant is bordered with a curved head, and the bottom of every interval with an inverted curve. By impressions met with on coins, we are led to suppose, that terminations of the same kind were adopted in other Grecian edifices. Balustrades are represented in the works of the earliest Italian writers, who might have seen them in the ruins of Roman structures; but none have been discovered in modern times. When a balustrade finishes a building where an order is employed, its height should be proportioned to that of the order it accompanies, and must be raised on a socle or plinth, so that its parts may be completely seen at a proper distance. When intended for service, it should be of equal height to a parapet in a similar situation, that is to say, not less than three, and not more than four feet six inches. In shape, the baluster consists of a square plinth, base mouldings, an ogee-shaped contour of body or middle part, an astragal and cup, consisting of a moulding under a square abacus. The plinth of the base, the swell of the body, and abacus of the capital, are generally in the same vertical straight line. The distance between the balusters should not exceed half the breadth of the plinth, nor be less than one-third. On stairs and inclined planes, the same proportions are to be observed as on horizontal surfaces. Formerly the mouldings were made to follow the inclination of the plane; but this is unpleasant to the eye, and is difficult in the execution; indeed, in situations of this kind, the use of balusters have been generally superseded by ornamental cast-iron work. The breadth of the balusters over an order, must be regulated by the heads of the shaft of the column, to which the die of the plinth, the bulk of the body, and the abacus, must be equal. When there is no order, the breadth of the die of the pedestal is never more than its height, and frequently less. The die of the pedestal is frequently flanked by half dies, particularly when the range is long.

Doors.
Plate
CLXXXVIII.

Doors, (see Plate CLXXXVIII.) in exterior walls, form apertures to gain an entrance into the buildings, or in interior walls for passing into apartments, or from one apartment into another. The former are again distinguished by the terms *door* and *gate*; a door is for the admission of men, a gate for horses and carriages; and as well as to houses, are inlets to cities, fortresses, parks, gardens, &c. Doors being of small dimensions, are commonly parallelograms, either arched or covered horizontally with lintels; gates being wider, are, unless they consist of piers only, always covered with arches. The general proportions for the apertures of both gates and doors, is, that the height be about double the breadth.

For doors, the minimum apertures are regulated that a man may pass easily through them; they are, therefore, seldom less than three feet wide, and six feet six inches high; but they are often varied in their dimensions, according to the height of the story and magnitude of the edifice. In private houses, four feet may be their greatest width; in churches, &c. they are frequently six feet in width. In gates, 8½ or 9 feet is the least admissible breadth; they are frequently from 10 to 12 feet.

Vitruvius, in his fourth book, has laid down rules for Doric, Ionic, and Attic doors, all of which have their apertures narrower at the top than the bottom; in these, the doors, when opened, shut of themselves; and also in opening, rise so as to clear a carpet, &c. These have also been partially introduced by modern architects, though this advantage is more generally obtained by other means.

It is a good proportion in small doors, to have their dimensions in the ratio of three to seven; and in large doors, of one to two. Inside doors must be regulated by the height of the apartment to which they belong; there is, however, a limit in this respect, because the difficulty of opening and shutting is increased by its weight; and therefore single doors of private houses should not exceed three feet six inches in breadth. The lintels of doors should be on the same level with those of windows. But in magnificent houses, where all the doors are frequently thrown open, they may be from six to eight feet, made in two leaves or divisions: here the proportion will be less in height when compared to the breadth. The apertures of exterior doors, placed in blank arcades, have their lintels usually on a level with the imposts or springing of the arch.

Principal door.

The principal entrance door ought to be in the middle of the length of the building; it divides the mass of front into more uniform portions; and the hall, vestibule, &c. are thereby placed in the centre of the apartments, to which they will have more convenient access, than if placed in any other situation. The doors which communicate between principal apartments, should be placed sufficiently distant from the side walls, to admit of furniture being placed there conveniently; for preserving an uniform temperature in apartments, there should be double doors, that is, two in the thickness of the partition wall.

Decorations.

For decorations to doorways, it is usual to have an architrave up each side, and along the top; and upon this is sometimes placed a frieze and cornice; the ends of the cornice are occasionally supported with trusses or consols, which stand upon the top of a pilaster. When the pilasters have bases and capitals, the projections are always kept within that of the architrave; the architrave over the capitals of the pilasters is similar to that of the door. Columns of some of the regular orders are sometimes introduced, supporting a regular entablature and pediments; but these, though proper enough for exterior, can scarcely be reckoned suitable for those that are between interior apartments. Outside doors are also frequently ornamented by rustic work; but rustics being imitations of the unfinished work of the ancients, appear improper when applied as ornamental. Doorways are also, in these northern climates, made in close porches, constructed in the shape of a part of a small Greek or Roman temple. When they are of a rectangular form, they admit of a doorway, with sufficient regularity and conveniency; but when circular, there is some trouble attending them; because, unless the door is also circular, it cuts off a segment, which creates an awkward appearance; and, upon the whole, we will venture to affirm, that although doorways are highly susceptible of decoration, yet the ingenious architect may contrive some much more suitable than any of the Greek orders; which being here so diminutive, are totally divested of that dignity which is necessary to produce a striking effect.

Door itself.

The door itself is either framed, battened, or ledged, and the materials are wood or metal. Formerly, in England, the doors were made of oak; in most houses they are now made of deal, and in some cases of mahogany; for strong closets for books, writings, money, jewels, plate, &c. the doors are made of cast iron. The ancients frequently constructed the doors of their temples of gold, silver, bronze, ivory, &c. As the particulars respecting the modes of preparing and framing doors belong to Joinery, the reader will, under that term, find it defined and illustrated.

Windows.
Plates
CLXXXVII.
CLXXXVIII.

In Windows, (see Plates CLXXXVII. and CLXXXVIII.), the size of the apertures depends chiefly on the circumstances of climate, aspect, proportion, and

Upper windows should be tallest.

destination of apartments; the thickness of the walls, and the number and distribution of the windows themselves. Much also has hitherto depended upon the fashion of the times; from the small proportion of ancient aperture until the slender masonry of the walls of Gothic edifices became merely frames for receiving the glass. In modern structures, where rectangular forms are employed, the breadth of the apertures serves to regulate that of the piers, though considerable latitude has been taken; yet, in plain walls, the most general practice limits the breadth of piers to be the same, or one and a half that of the aperture; the former, when circumstances admit, appears the most perfect; but these proportions must, of course, be occasionally varied, to admit of external and internal decorations. The sills of windows should be placed at a height above the level of the floor, to form a convenient parapet, but not obstruct the view; and this is varied from two feet and a half to three feet and a half. In elegant apartments, the sills are frequently on a level with the floor, or a step or two above it; in the latter case, the heights of the apertures are made more than double their breadth. It is common in different stories to have different heights, decreasing in the upper stories, until in attics they are made under a single square; this, when economy leads to making the upper stories very low, is unavoidable; but when elegance of external appearance is studied, the upper windows should be made the tallest. Windows ought to be placed vertically above each other, and not too near the angles of the building. Where the walls are thick, their jambs may be splayed or bevelled; that is, to make an acute angle with the front line, in order to admit more light into the apartments. In northern climates, sky lights ought, as much as possible, to be avoided, as being liable to admit cold air, rain, and snow. Where they are necessary to light halls and staircases placed in the central parts of the structure, the architect would do well to contrive that the lights be fixed in a perpendicular direction, and be properly protected on the top. An odd number of windows in the same front is preferable to an even number; for as it is requisite to have the entrance-door in the middle of the length, an even number, regularly disposed, would cause a pier to be over the doorway, which is inadmissible. An odd number is also preferable in a large apartment, as a pier would cast a gloom in the middle part of the floor. In edifices of importance, windows are usually ornamented in the same manner as doors, and subject to similar observations. If attics are introduced, instead of leaving the windows, as has hitherto been the practice, plainer than those below, they should, in our opinion, be rendered a part of an ornamental member, to be continued along the upper part of the whole line of front. Mixtures of windows of different shapes is in general to be avoided; but if a Venetian window is to be introduced, it should be insulated by a break or some other device; the entablature should be continued along the top of the pillars which form the divisions, and that even if an arched opening be necessary over it. In winter apartments in cold countries, two sets of sashes are placed in the thickness of the walls. The mode of preparing, constructing, and fixing the frames, sashes, linings, shutters, and dressings, will be detailed in the article JOINERY.

Chimneys. PLATE CXC.

A CHIMNEY (See Plate CXC.) consists of an aperture in the wall, to receive a stove or grate, with fire to heat the apartment; and on this account it is also named a *Fire-place*. From it a vacant space, named a vent, shaft, or flue, is carried, within the thickness of the wall, to the level of the top of the roof, to convey away the smoke. The bottom of the fire-place should be laid with square tiles, stone, marble, or an iron plate, in order to receive the cinders and ashes; this is termed the *Inner hearth*. Upon a level with this, or a little above it, and immediately before the fire-place, a space equal in length to the breadth of the chimney, and about two feet in breadth, should be laid with the same sort of materials as the inner hearth; it is termed the *Slab*, and is laid either in a wooden boxing, containing sand and mortar, or upon a flat brick arch, which has been turned between the wall and a trimming-joist in the floor. The front and vertical sides of the chimney aperture are termed *Jambs*, and are composed of stone, marble, wood, or iron. The part which reaches across the top of the aperture is called the *Mantle*, and is of the same sort of materials as the jambs. As in thin walls, the part which the chimney occupies is projected into the room, in this, what is over the chimney, is termed the *Breast*. Within the fire-place, the parts which reach between the jambs and back, are named *Covings*. Where the space is contracted from the size of the fire-place to that of the flue, it is called the *Gathering wings*, or *Throat*. The portion of the chimney which rises above the roof, is named the *Chimney top*. Where several flues, either in the wall or at the top, approach very near each other, the partitions between them are named *Withs*; and the whole is termed a *Stack*. In rooms of ordinary dimensions, the flues, in rough stone walls, are from 12 to 14 inches square; in hewn stone or brick-work, about 10 by 14 inches; but the section must be enlarged in rooms of large dimensions, kitchens, &c. As soot is apt to gather in the angles of square flues, the circular form is preferable. They should be made quite smooth within, and free of quick bendings. It is of advantage to have the flues a great height; but if raised much above the level of the roof, it is difficult to render them ornamental. Inigo Jones is the only British architect who has performed it with success.

As much of the comfort of an apartment depends upon its being free of smoke, and much economy in causing the heat to be reflected into the room, instead of suffering it to be unnecessarily absorbed by the materials, or dissipated in the flue, &c. great attention is necessary in fitting up the fire-place. For economy, stone which will stand the fire, is preferable to metal. The side covings should be levelled, or wholly circular; and the opening at the back of the fire-place into the throat should not exceed four inches in breadth; frequently one inch and a half is sufficient. With register-stoves this can be regulated to great advantage. The throat part should fall back from this aperture, and, in general, no air should be admitted into the throat, but what passes over the fire; it is therefore advisable to fit up the fire-place very accurately, and place the front of the grate forward to the line of the face of the wall of the apartment. In countries where stoves are used, it is customary to place them altogether before the face of the wall. This admits of much decoration, and also throws the greatest part of the heat into the room.

Chimneys have always been considered important features, but the style of decoration has varied greatly in different ages. In the Norman castles, they were frequently large, and accompanied by rude pillars, sculptures, and ornamented mouldings. After the revival of Roman architecture, the whole space between the fire-place and the ceilings, called the chimney breast, was covered with architectural decorations of great labour and expence. Wood was succeded by stucco work and ornamented pannels, to receive paintings; but of late these have been abandoned, and the chimney has been reduced into the smallest possible bounds, making it, for elegance, depend upon the marble dressings and highly polished and engraved steel register stoves.

Ceiling.

Plate CXC.

The name of *ceiling* (see Plate CXC.) is given to the work which conceals the naked timbers of the roof of an apartment. The Normans generally left the framing timbers uncovered, and ornamented them with mouldings and sculptures; but however much ornamented, they, in that state, always retained the name of roof. The Romans covered their roofs, and it is from the remains of their public buildings, that the moderns, after the revival of that style, derived their manner of constructing ceilings. Ceilings are either *flat*, or *coved*, or partake of both. Flat ceilings are divided into large compartments, ornamented with foliage or other devices. Coved ceilings have their sections either less than, or equal to semicircles. Ceilings which are *flat* and *coved*, are of modern invention; they have their middle part flat, and that next the walls coved. Compartment ceilings are constructed either by raising the mouldings above the general surface, or by sinking the pannels below it; or they may be partly raised and partly sunk. Amongst the ancients we find the pannels in squares, hexagons, and octagons; triangles were rarely used.

Temple of Peace.

Balbec.

In the porticos of ancient temples the ceilings were mostly divided into equilateral equiangular parts; the pannels were deeply recessed, and the prominent surfaces represent the antique method of framing the beams of floors; the mouldings, on the sides of the pannels, were sunk like inverted steps, in one or more degrees frequently enriched, and the bottom of the pannels, in general, decorated with roses. In Roman works, the pannels are always parallel, or of equal breadth, which admits of no other variety, when squares are introduced; but hexagons will join with each other, or the interstices will form lozenges or equilateral triangles; octagons form two varieties, viz. that of their own figure, and that of the square in their interstices. This sort of compartment is termed *coffering*, and the recessed parts are called *coffers*, which are used in vaulted or plain ceilings. The borders of the coffering is generally terminated by belts charged with foliage, and bordered with guillochis, as in the Temple of Peace at Rome. In the ceiling of the Temple of Balbec, coffers are disposed around the cylindrical vaults in rows, one row rising over each intercolumn; and a projecting belt ornamented with a guillochi between every row of coffers, corresponding to two semi attached columns in the same vertical plane, which support the springing of the belt. This practice has been imitated by the moderns, in cupolas and cradle vaults; the latter decorated by frets, guillochi, foliage, small pannels with roses, and large pannels with historical subjects, frequently in bold relief.

Ceilings painted.

The grounds of compartment ceilings may be gilt, and the ornaments white, party coloured, or streaked with gold; or *vice versa*, the ornaments may be gilt, and the grounds white pearl, straw coloured, blue, or any tint that will suit the ornaments. In some cases, the ceilings are either painted wholly, or in various compartments only.

General remarks.

The mode of constructing the modern ceilings having been copied from the remains of ancient public buildings, it, in general, proved too heavy for the apartments of private dwellings. This defect was first remedied by the delicate taste of Mr Adam, who introduced a much lighter style, more diversified, and better suited to private apartments. The pannels were formed by slender mouldings, the decorations of elegant stucco ornaments, or painted devices; and the whole grounds also painted to relieve the other decorations.

Stairs.

STAIRS form the means of communication between the different stories. They are regulated in height and breadth so as to render the step commodious, and the length is suited to the magnitude of the edifice and the purpose to which it is to be appropriated. The average height is about six inches, the breadth 12 inches, and the length is seldom less than three feet, generally more. The space in which the steps are inclosed, is termed *staircase*, and is square, circular, elliptical, or triangular, but rarely polygonal. The steps may be constructed of *marble, freestone, wood*, &c.; they may be supported at both ends, or at one only; when the latter, it is usually the broadest, though in small wooden stairs, the steps are sometimes made to project from a newel to which the narrow ends are fixed.

In the construction of stone stairs, supported at each end, the inner end of the steps may either be fixed into a solid newel, or be tailed into a wall surrounding an open one; or where elegance is not an object, if the newel do not exceed two feet and a half, the steps may be supported by a solid pillar, though when the newel is thicker, it will be cheaper to surround the open space with a thin wall. In stairs of a sunk story, where there is a geometrical stair above, the steps, next the newel, are generally supported on a dwarf wall.

Geometrical.

Geometrical stairs have their outer ends fixed in the wall, and the under edge of every step supported by the edge of the one below it; being constructed with *sally* formed joints, so as to prevent them from descending in either the inclined direction of the stairs, or in a vertical direction. The upper *sally* of every step forms an interior obtuse angle, called a *back rebate*, and the lower *sally* forms an exterior one; the joint occasioned by these *sallies*, is called a *joggle*. The upper part of the joint may be level from the face of the riser to about one inch within the joint; the plane of the tread of each step is thus continued about an inch within the surface of each riser; the lower part of the joint has a narrow surface perpendicular to the rake of the stair at the end next the newel. In stairs, constructed of most kinds of stone, the thickness of every step, at the thinnest part of the end next the newel, need not exceed two inches, for steps of four feet in length, measuring from the interior angle of every step perpendicular to the inclination. Their thickness at the interior angle should be proportioned to their length; allowing two inches for the thickness of the internal angle at four feet; the thickness of every other stair, at the same place, will be equal in inches to half the length in feet; thus, a step five feet long will require to be two and a half inches in thickness at the interior angle.

Stone platforms, or half or quarter spaces, of geometrical stairs, consist of one or more stones, as they can be procured; when two or more are used, the first stone should be laid upon the upper step, with its edge wedged into the wall; the next stone must be joggled or rebated into the one just set, and its end also fixed in the wall. The same mode must be pursued with the remaining stones, till the platform is completed. In cases where a second flight of stairs is required, the last stone of the platform becomes an abutment for the lower step of the next flight, and the joints must be joggled as in the former flight.

Geometrical stairs, constructed of stone, depend upon the following principle: that every body must be supported by three points at least, placed out of a straight line; and consequently, if two edges of a body, in different directions, be secured, they will become relatively immoveable; such is the case in a geometrical stair; one end of the step is always tailed into the wall, and one edge rests either on the ground or on the edge of the inferior step or platform.

Wooden stairs.

The practice of *wooden stairs,* (which also includes the constructing and fixing the handrails for those of stone,) falls under the article JOINERY, to which we must refer. But besides the before mentioned materials, stairs may be constructed with *cast iron,* which would, in the case of fire, have advantages over either of the former. The facility with which the several parts may be cast and fixed, and the light and elegant forms which may be introduced, at a comparatively moderate expence, lead us to press this new mode upon the attention of the young architect.

Cast iron.

The staircase has always been considered a principal feature, not only in the private dwelling, but also in the public edifice. It is usually placed so as to be seen from the hall or vestibule, and centrical for communicating with the public or principal apartments; it is frequently decorated with columns and pilasters on the sundry landings; it is generally terminated at the top by an elegant skylight window, and has its walls enriched with pannels for paintings, and niches for statues or busts.

Decorations.

Egypt.

DECORATIONS anciently, (besides what belonged to the orders,) consisted of sculpture and painting. In the palaces and temples of Upper Egypt, the walls are completely covered with sculptures, and the ceilings by paintings. In the numerous splendid tombs both the walls and ceilings are frequently covered with paintings; but here it is profusion rather than design or execution which attracts admiration. In the ruins of the palace of Persepolis, and tombs of the kings, the sculpture is equally profuse, and the execution just as imperfect. The fine genius and taste of the Greeks reformed both sculpture and painting. Their principal and boldest features consisted of animal figures, and it is difficult to determine whether the taste in designing or skill in the execution merits most admiration. The subordinate members are decorated with representations of vegetable substances; where great delicacy is observable, they are generally in low bass relief, and the honeysuckle plant predominates. Their paintings were chiefly historical subjects, as the battle of Marathon, by the brother of Phidias, in the temple of Jupiter Olympus at Elis. In Roman architecture the profusion of sculpture became excessive; the skill of the workmen long continued very perfect, but the taste of the architect greatly degenerated. Some of their triumphal arches and historical columns, where the utmost efforts of sculpture are appropriate, have through every age continued to command the admiration of mankind; but in their later temples, palaces, and baths, the profusion is tiresome and disgusting. In modern times, although architecture was, for some ages, overloaded with minute sculptures, it was by degrees much chastened, and excepting on interior stucco work, it has, for some time past, been almost wholly abandoned. On the other hand, the use of painting has been much extended, and is, indeed, in all interior works become universal, excepting where the walls are covered with *paper,* a modern invention of great beauty, comfort, and economy.

Persepolis.

Greeks.

Romans very profuse.

Statue or bust.

One species of sculpture has been uniformly practised by both ancients and moderns, that is the isolated *statue* or *bust.* The ancients decorated their forums, basilicas, temples, theatres, and baths, with statues of their deities, philosophers, heroes, legislators, &c. and the moderns have done the same thing in their churches, palaces, houses, squares, gardens, public walks, &c. The statues are placed either singly or in groupes; they are either raised on pedestals standing quite isolated, or in recesses termed *niches;* if in niches, the distance between the outside of the statue and the sides of the niche should never be less than one third, nor more than one half a head. Statues are frequently placed on a *plinth,* whose height may vary from one third to one half a head. Besides the before mentioned situations, statues are sometimes placed before the dwarf pilasters of attic stories, as in the arch of Constantine, the Corinthian colonnade at Thessalonica, and at Somerset Place in London.

Plan.

PLAN, by this term is understood the drawings or representations of the intended structure; they consist of three sorts: 1st, Shewing the shape, dimensions, and relative situation of the several apartments. 2d, Shewing the appearance which the external faces of the edifice will have when completed; and 3d, Sections shewing the heights and mode of finishing the principal apartments.

It will be readily perceived, that no fixed rules can be laid down for forming plans which shall, in all cases, be applicable. The architect, in making the design, must be regulated by the climate, the situation, the purpose to which the edifice is to be appropriated, the nature of the materials to be employed, and the customs and habits of the people; and the latter not only vary with their rank in society, but are continually changing in every rank, as must be evident to the reader from perusing the sketch we have given of the history of architecture. The utmost therefore we shall attempt, will be to produce and explain specimens from the works of the most celebrated architects, since the revival of Roman architecture; and make some general observations upon the modes now practised in Britain.

Revival of Roman architecture.

Buscheto.

In tracing the progress of the revival of Roman architecture, it is necessary to remark, that in 1016, Buscheto, a Greek of the isle of Dulichio, was employed to construct the cathedral of Pisa, which he did with marble columns and a dome. He had many disciples, and may be reckoned the founder of modern architecture in Italy. But the earliest specimen we shall produce, is the plan and section of the cathedral of Santa Maria del Fiora at Florence, which will be found in Plate CLXXIII. It was begun in 1288, by Arnolf Lusii, a Florentine architect, and left, after he died in 1300, for 120 years in an unfinished state, as no person could be found who would undertake to construct the dome. In 1420, Filipo Brunelleschi, having previously, with great diligence, studied the remains of ancient architecture at Rome and Florence, proposed a scheme to complete that difficult work. He solicited the curators of the fabric to have it examined by a convocation of Italian and Oltramonte architects, who complied with his requisition; but these timid artists considered the project so extravagant, that they hissed him out of the assembly. They proposed to raise a mound of earth interspersed with pieces of money, and on its top, when properly moulded, to turn the dome, and then to suffer the populace to remove the earth for the money it contained. This miserable expedient was, however, rejected; and the persevering Brunelleschi, after having returned to Rome, and again examined its ancient buildings, was recalled, and permitted, after making some experiments upon a small scale, to commence his favourite project. He continued to direct the works for 20 years, and, before his death in 1440, had closed in the dome at the foundation of the cupola or lanthern, for which, and the globe and cross, he left de-

Santa Maria del Fioro at Florence.

PLATE CLXXIII.

Brunelleschi.

signs and instructions, and which were finished in 1456. From the pavement to the bottom of the cupola the height is 277 feet, the diameter of the dome is 133 feet, and it rises about four-fifths of this diameter. It is of an octagonal form, and consists of two shells with a space between them, the tapering being very gradual. It was built without the aid of scaffolding. We have no account of the manner in which the two shells were connected, or what security it derived from *hooping*, though it is probable that precautions of this nature were adopted, after the practicability of the scheme had been so strongly disputed. The complete success, however, had acquired the architect so much respect, that he was interred within the edifice, and honoured with a public funeral. The general outline of the cathedral is in the form of a Latin cross. The nave and side aisles, which are divided by large piers, taken together, compose a parallelogram; the terminations of the transept and chancel are externally semi-octagons. These, by diminishing as they ascend, and having their vaulted roofs abutting against the sides of the walls which bear the dome, are judicious supports, and contain the elements of the flying buttresses afterwards adopted in Gothic structures. The neck of the dome rising perpendicularly for upwards of 50 feet above the top of these vaults, the interior of the dome and space below, are from thence lighted by means of a circular window placed in each side of the octagon, at about half the before mentioned height; this prevents the necessity of their being placed in the dome, and thereby destroying the simplicity of its outlines.

St Peter's at Rome.

Plate CLXXIV.

The next specimen we have selected, is the cathedral of St Peter's at Rome, erected in place of that which had been built by Constantine, in 324, upon the circus of Nero: A plan and elevation will be found in Plate CLXXIV. This is not only the most magnificent Christian temple, but in magnitude of outlines, and variety of parts, far exceeds any of the edifices constructed by the Greeks or Romans; and although the ground plan does not occupy a space quite equal in extent to that of Karnac, in the Egyptian Thebaid, yet the having about six times its elevation, gives to the Christian temple a decided superiority. The extreme length of St Peter's is 720 feet; the breadth 510 feet; and the height from the pavement to the top of the cross, 500 feet.

Bramante.

Baldassar Peruzzi.

Michael Angelo.

The design was made by Bramante of Urbino, in consequence of directions from Pope Julius II.; this pontiff having resolved to pull down the old church, and in its place to construct another to surpass every thing of the kind then extant. The architect, zealous to accomplish so magnificent a project, formed various designs, especially one, in which the front was placed between two steeples, and with a dome resembling that of the Pantheon, both externally and internally, as represented in medals made by the celebrated Caradossa, and struck under Julius II. and Leo X. But the insulated temple built by Bramante without the walls of Todi, in the duchy of Spoleto, in the form of a Greek cross, with a beautiful cupola in the middle, appears to have been the model of St Peter's. This great work was begun with much zeal and industry in 1506, but suffered a serious interruption by the death of both the Pope and architect, which took place in 1514. The work was however resumed and continued, under the direction of twelve architects, for 135 years. The plan was considerably varied under Leo. X. by Baldassar Peruzzi; and many parts of the elevation, and the whole of the dome and cupola, as executed, were designed by the celebrated Michael Angelo Buonarotti. This edifice, therefore, contains the best specimens of design of the ablest architects who flourished during a period in which the revived Roman style was carried to the highest perfection which it reached in Italy. A full description of this magnificent edifice will be found in the superb work of Carlo Fontano; the plan and elevation we have given being carefully and minutely made, will afford a distinct idea of the style and arrangement, both externally and internally. We shall therefore here confine ourselves to some general observations respecting them.

Great entrance resembles the Temple of Peace.

Interior well disposed.

Dome.

In the plan the great western entrance bears some resemblance to that of the Temple of Peace, having seven passages into a porch 230 feet long and 40 feet wide; the areas of the nave, choir, and transept, form a perfect Latin cross; the space which encompasses the plan of the dome, with its supporting piers, forms a square, having a small circle at each angle, the whole being admirably disposed for simplicity, strength, and magnificence; the side aisles, instead of being each of consequence when taken lengthwise, seem rather to consist of a number of distinct chapels, ranged along each side of the nave; but the whole interior of the fabric is so completely occupied by pilasters, columns, recesses, and niches, that nothing is left imperfect; and the breadth of the ground plan being so great in proportion to its length, conveys an idea of stability. The dome forms nearly an ellipsoid on the exterior, rising vertically from the base, and at about the height of 50 feet branches into two thin vaults, separating gradually as they rise; thin partitions are dove-tailed into each shell to connect the two together, so that the whole is rendered at once light and firm.

External outlines.

Externally in the elevation, as viewed from the westward, the height to the summit of the dome, (which includes the apparent mass of building) exceeding only in a small degree the breadth of the western façade, and the height to the top of the cross bearing the same relation to the bread that the transept does, bring the outlines of the whole mass nearly within an equilateral triangle, and thereby convey an idea of stability, equal to the before mentioned proportions of the general plan.

General remarks.

A building composed of columns and pilasters 9 feet diameter, and the whole order upwards of 100 feet high upon a façade of 400 feet, and of nearly double that extent when taken in perspective as far as the transept, is certainly one of the most imposing objects which art has accomplished; a dome resting upon a pedestal, encompassed by a colonnade 50 feet high, having its base elevated 200 feet above the surface of the earth, also commands an equal degree of admiration; for the extent of the outlines rivals the Egyptian pyramid, and the skill displayed in the construction far exceeds any thing connected with these enormous heaps of almost rude stones. But while we admit, in the fullest manner, the merits of this magnificent work, we consider it our duty to notice defects, which appear to lessen the effect which it might have produced.

Defects.

Too many breaks.

To those accustomed to examine the outlines of the façade of the Greek temple, the portico of the Pantheon at Rome, or of the square house at Nismes in France, and who have considered the associations they produce upon the principles so justly defined by Mr Alison in his *Essay upon Taste*, it will be evident, that the multiplicity of breaks in the western façade destroy the simplicity of the horizontal lines of the entablature, which ought to represent wooden beams; the mind is perplexed in determining how timber could be worked or connected in this manner, and is provoked to observe

Pediment too small.

Too many small parts.

this deviation without any good cause; the same objection is more palpably evident in the colonnade which encompasses the pedestal of the dome; here the columns are placed in pairs, and there is a break over each pair by which their connection with each other is totally interrupted. In the great order, the pediment, instead of being rendered a bold feature, by extending over the whole space where columns are introduced, and thereby affording room for sculpture, (the only purpose, in a square front, which renders a pediment admissible), is confined to four columns only, a thing unfit even in a private dwelling. Instead of preserving the face of the building plain and simple, to accord with its great outlines and gigantic order, the entrance doorways are of various dimensions and shapes, and the whole building is covered with small tablets, and perforated with small windows, even the dome itself, circumstances much to be regretted. With regard to the nature of the construction of the masonry of St Peter's, we are informed by Rondelet, an eminent French architect, that the outside of the walls is composed of a thin coating of cut travertine stone, that the middle is lined with bricks covered with stucco, and the space between filled with small irregular rubble stone mixed with mortar, that the counterforts are of cut stone, and that the ardour of Bramante hurried on the work with so much precipitation, without taking effectual measures to unite the different parts, and prevent unequal sinking, that by the time the four first arches had been completed, considerable fractures made their appearance;—that the architects who succeeded him, not being aware of the real cause of the fractures, nor considering that two of the pillars were placed upon the foundation of the circus of Nero, and the other two upon earth softened by the water from the adjacent sloping ground, thought only of increasing the points of support. San Gallo, an unprincipled builder, who was brought from Florence, enriched himself by performing the work very imperfectly; and even under Michael Angelo, the walls were filled with irregular stones, without care, arrangement, or ties. These are the true causes of all the fractures of the dome, &c. Indeed the architects, instead of studying the solidity and connection of the work as engineers, acted as painters, chiefly intent upon the appearance and decorations.

Private dwellings in Italy, from Palladio.
PLATE. CLXXVII.

From these public works we shall next proceed to the private dwellings of that æra, and, as the best authority, we shall select three specimens from Palladio, all of which will be found in Plate CLXXVII. Figs. 1. and 2. represent the plan and elevation of a town house, the lower rooms are in part sunk, and also rise 5 feet above the ground; over these are two principal stories, the lower of which is, in front, of the Doric, the upper of the Ionic order; in the lower of these a portico is extended along the whole front, and all the apartments have their ceilings vaulted; in the upper story the hall is in the middle of the front, and on each side there is a lofty vestibule. A great proportion of this edifice is occupied by halls, vestibules, stairs, and porticos; it is evidently fit only for a warm climate. The two orders being continued along the front without unnecessary breaks, and there being two regular rows of pretty lofty windows with flat tops, preserve an air of simplicity, but the upper row ought to have been higher, for there is too much dead wall over them.

Figs. 3. and 4.

House in the suburb of a city.

Figs. 3. and 4. represent the plan and elevation of a moderately sized house in the suburbs of Vicenza. It was built by Palladio in a fine situation for Signor Almerico; it has been much admired, and Mereworth castle in Kent was built upon the same model by Colin Campbell in 1723; the four vestibules have a fine effect, and the circular hall, with four entrances, is simple and elegant. In a square of 80 or 90 feet, four large, and an equal number of smaller apartments, may be obtained upon one floor; there is plenty of space for domestic offices below, and the same for bed-rooms above the principal story; the small triangular stairs without light, are objectionable; but as they are only for communicating with bed-rooms, the inconveniency is the less; those to the lower story may have borrowed lights.

Villa in th country.
PLATE CLXXVII. Figs. . an 6.

Figs. 5. and 6. represent the plan and elevation of a villa designed by Palladio upon the Brenta, for Sieur Moconico, a Venetian noblemen; it consists of a square encompassing a court, in which is a peristyle consisting of two heights of columns, the lower of the Ionic, the upper of the Corinthian order. From each external angle of the square is projected a circular portico, which connects with the offices. The principal entrance has a bold projecting portico of eight columns of the Composite order, 40 feet in height, and crowned with a pediment; behind the columns are pilasters 2 feet broad and 15 inches thick, which support an open gallery at the height of the principal story. In the middle of each external side there is a porch or loggia, formed each by four columns and two pilasters, standing in a line with the outer wall; these rise also to the height of the side walls, and are crowned with pediments. In the back front eight semi-columns are attached to the wall. On this side of the square there is a saloon or oecus 60 feet long and 30 feet broad, which is divided by two rows of eight columns each; over this, in the upper story, is a hall of the same dimensions, but without columns. The principal stair is in the peristyle of the inner court, on the side opposite to the great entrance. This edifice is in the style of the most magnificent Italian villas, and being the work of the ablest architect which that country has produced, must be admitted as a perfect specimen; the elegance of the elevation, however, appears injured by the smallness of the windows, and by the height being divided by a clumsy cornice; the roof also appears too heavy for the general airiness of character, and the elevations of the ends of the wings or offices are much too mean.

List of Ita lian architects and their works.

Although our limits will not permit us to adduce more specimens of the Italian architecture, we shall, in order to afford the reader a more comprehensive view of the rapid and extensive progress which the Roman architecture made in the course of two centuries, subjoin a list of the most celebrated Italian architects, with a statement of the principal works in which they were engaged.

Filipo Brunelleschi, born 1377, died 1444. His works and designs were as follow:

Church of Santa Maria del Fiore, at Florence.
Sagresty, and great part of the church of St Lorenzo.
The Capitolo de Pazzi in Santa Croce.
The Church Degli Angoli, an octagon, for the family Degli Scolari.
Model of the palace for Cosmo de Medici.
The palace Pitti, up to the second row of windows.
Model of the Casa de Busini.
Model of the house and loggie degli Innocenti.
The portico of the Hospital de Convalescenti.

Continuation of the Palazzo de Capitani.

A villa out of the gate of St Nicholas, for M. Luca Pitti,

Abbey of the Canons regular of Fiesole.

Leon Baptista Alberti, born 1398, died 1472 or 1480.

Repair of the conduit Aqua Virgine at Rome.

Design for covering the bridge of St Angelo.

New works and embellishments of the church of St Francis at Rimini.

Church of St Andrews at Mantua.

Portal of the church of Santa Maria Novella, at Florence.

Corinthian loggie and Doric front of the Palazzo Rucollai.

Chapel for the Rucollai family (reckoned fine.)

He wrote ten books, entitled *Re-ædificatoria.*

Bramante of Urbino, born 1444, died 1514.

Palazza della Cancellaria. Church of St Lorenzo in Damaso.

Palace built in 1504, by Cardinal Adriano da Corneto, and presented by him to the King of England.

Palace of the Dukes of Sora nella regione di Parione.

Palace of the Marchesi Corsini, begun from his design.

The great court, 400 paces long, between the old Vatican and the Belvidere.

The repository in the Belvidere, for the Laocoon, Apollo, Antinous, &c.

Little round temple in the cloister of St Pietro in Montorio.

Insulated temple without the walls of Todi, in form of a Greek cross, with a cupola, thought the model of St Peter's.

St Peter's Church.

Raphael Sanzio di Urbino, born 1483, died 1520.

Pallazza Ugoccioni, in the great ducal palace at Florence, since named Pandolfini.

The stables of Agostino Chigi alla Lungara, near the little Farnese, Rome.

Palazzo Caffarelli, near St Andrea della Valle.

House for himself in Borgo Nuovo (it was removed for the portico before St Peter's.)

Baldassare Peruzzi, born 1481, died 1536.

Palace alla Lungara, near Farnesina.

Models for the front of St Petronio, at Bologna.

Additions to the palace of Count Gio. Battista, Bentivoglio, at the same place.

The portal of the church of St Michele in Bosco, a little way from Bologna.

A dome, and the church of St Nicholas, at Carpi, in the state of Modena.

Variations of the plan of St Peter's at Rome, by order of Leo X.

The deposit of Adrian VI.

Two palaces for the family of Massini at Rome.

Designs for two villas of the S. S. Orsini, near Viterbo.

Palace of the Marquis of Silvestri, opposite St Lorenzo in Damaso.

Michele Sanmicheli, born 1484, died 1559.

Many military works, which we decline noticing in this place.

Model of the monastery of the nuns of St Biagio Catoldo at Venice.

Palace de Cornari a S. Paolo, and that of Grimani, upon the great canal.

Villa Soranzo, at Castel Franco, between Padua and Trevigi.

A deposit in the church of St Antonio at Padua.

Design for the front of Santa Maria in Organo.

The palaces Canessa, Beviacqua, Pellegrini, Pompei, Verzi, are all his.

The portals of the Pretorian and Prefectitial palaces at Verona.

Michael Angelo Buonarotti, born 1474, died 1564.

The Medicean Library at Florence.

The Sagrestry Nuova at St Lorenzo, in the same place.

St Peter's church at Rome, (he made a model of it in 15 days, which cost only 25 crowns.)

Designs for rebuilding the capital.

Pedestal for the equestrian statue of Marcus Aurelian.

The Cappella Strozzi at Florence.

The college of the Sapienza at Rome.

Giulio Romano, born 1492, died 1546.

Villa Madonna at Rome.

The church of Madonna del Orto.

Palazza Cicia Porci, in the Strada de Banchi; also that of the Cenci.

The palace T, a little way out of Mantua, (one of the finest edifices in Italy.)

He repaired and enlarged the Ducal palace, and built at Marmicuolo.

It was usual to say, that Mantua was a creation of Giulio Romano. He was appointed architect of St Peter's of the Vatican.

Sebastian Serlio was a distinguished artist in 1530, died 1552; he was a pupil of Baldassare Peruzzi. He was employed in France at the Louvre, Fontainbleau, Tournelles, &c. for Francis I.; and wrote seven books on geometry, perspective, and architecture.

Pirro Ligerio, died 1573.

The Pallazine in the wood of Belvidere.

The palace of Lancelotti in Piazza Navona.

He also acted as a civil engineer for the Duke of Ferrara.

Giacomo Barozzi, (Vignola), born 1507, died 1573.

Design for the front of St Petronio at Bologna.

Facciata di Banchi, a sort of wing to that cathedral.

Palace for Count Isolani, at Minerbio, near Bologna.

Plan for the ducal palace at Piacenza.

Churches of Mazzana, St Oreste, della Manno, degli Angeli, in Ossivi.

A beautiful chapel in the church of St Francesco in Perugia.

At Rome, the Acqua de Trevi, a villa without the Porta del Popolo, named Papa Guilio.

That part of the Farnese palace which contains the famous gallery painted by the Caracci.

On the Flaminian way, a chapel named St Andrea de Ponte Molli.

At Rome, he refitted the edifice now called the palace of Florence.

Portal of Lorenzo in Damaso.

Practice.

Church del Gesu (of which his part is good.)

The palace of Caprarola, about 30 miles from Rome, (his greatest work.) He also designed the Escurial in Spain.

He wrote a Treatise on the Five Orders, published at Venice, in 1570.

He conducted the Canale del Naviglio into Bologna.

Andrea Palladio, born 1508, died 1580.

The public palace at Udine, (at 22 years of age.)

Portico inclosing three sides of the Hall of Justice at Vicenza (about the same time.)

Front of the great church of St Petronio at Bologna.

Public palace of Brescia.

Olympic theatre at Vicenza, begun 158, (his greatest work.)

Church of S. Giorgio Maggiore, Refectory and Monastery.

Front of the monastery of S. Francesco della Vigna; del Redemptore, &c.

Repairs at the ducal palace at Venice.

At Vicenza, Santa Maria Nuova; Palazza Prefettezio; façade of the Palazzo Tornieri; that of the Pal. del Conti L. Schio.

And in his published works may be seen a description of nine town houses, and 24 country villas, many of them very commodious and magnificent. We have, in Plate CLXXVII. given plans of a town house, one in the suburbs, and one of a fine villa in the country, all from this excellent master. These specimens, by their extensive and airy colonnades and porticos, are evidently better calculated for an Italian than a British climate, but their general distribution is deserving of attention, and the whole are expressive of the manner of the age, country, and architect.

Plate CLXXVII.

Vincenzo Scamozzi, born 1552, died 1616.

At Venice, the deposit of the Doge Niccolo da unc Ponte, in the church Sa. Maria della Carita.
- Museum to the Library of St Mark.
- Continuation of the Procuratie Nuove in the Piazza of St Mark.
- The palace Cornaro, on the great canal, including the magnificent court.

Vicenza, the palace Trisino, now Trento.

Florence, the second story of the palace Strozzi.

Genoa, Palazza Ravaschieri, of three stories, Rustic, Ionic, Corinthian.

Sabonietta, in the Mantuan, a theatre after the ancient model.

Saltzburg, the cathedral.

Six of his books on architecture were published in 1615, viz. 1, 2, 3,—6, 7, 8.

From the foregoing statement, which includes only the works of the most celebrated Italian architects, it will be readily perceived with what ardour architecture had been pursued; and when to these are joined the ancient works still existing, it will be evident what a rich field of study Italy must prove for the zealous artist; since Rome, Florence, Venice, Vicenza, Mantua, Genoa, Verona, Padua, Bologna, Piacenza, Ferrara, with their adjacent country residences, all exhibit splendid specimens of architecture.

Practice of architecture in Britain.

We have less regret in leaving this justly celebrated peninsula, by having next to proceed with the practice of another country, still more important amongst modern nations—that is Britain.

Practice.

St Paul's London.

Plate CLXXIV.

Although later in point of time than some other specimens we shall adduce, yet, in order to preserve the progress of domestic architecture more entire, we shall first give a specimen of public buildings; and have, for this purpose, selected St Paul's cathedral, which was erected in London from a design and under the direction of Sir Christopher Wren. In Plate CLXXIV. the plan and elevation are drawn to the same scale as St Peter's at Rome. This comparison renders the disparity in size very conspicuous; but when it is considered, that the Italian temple was constructed at the joint expence of all the richest countries in Europe, and that the English temple was built at the expence of that nation alone, and immediately after the city had been destroyed by the great fire in 1666, its magnitude will appear not a little surprising. In taste and scientific skill, the architect was fully equal to any of his predecessors in this school; but the funds being limited, and materials of large dimensions not easily procured, he was prevented from adopting his favourite design, and obliged to substitute one in which the individual members were more minute.

St Paul's compared with St Peter's.

In the plan of the building, as executed, the dome is placed nearly in the middle of the length of the nave, or middle aisle; and as the terminations of the transept are square, the shape of the cross is not only *internally* different from that in St Peter's, but is *externally* more distinctly defined. In St Peter's, the length of the middle aisle, from the western entrance to the extremity of the choir, is only about eight times its width. In St Paul's it is above eleven times, which adds much to the imposing effect of the internal perspective. The breadth of the side aisles in St Paul's, bears a greater proportion to that of the middle one; and the form is more distinctly continued through the whole length of the edifice than in St Peter's. The piers which support the dome, are, in St Paul's, well disposed to afford stability, without too much crowding the space on the pavement. Immediately under the dome, a greater degree of simplicity would have been preserved, if the entire order had, as in the original design, reached sufficiently high to receive the whispering gallery upon the entablature, instead of resting, as it now does, upon large arches and their spandrels. Externally, the height of St Paul's is greater, in proportion to its breadth, than St Peter's, but not so much as materially to lessen the idea of stability, which is also well preserved by the square terminations of the projecting part of the transepts. This relative proportion creates a greater degree of apparent elevation, than if the edifice had more breadth. The dome is elegantly shaped; and the pedestal, or neck, upon which it immediately rests, being considerably raised, is the means of shewing the dome to advantage; while the order which supports this neck, having its columns distributed at equal distances, and well relieved, and having its entablature continued quite round, without any break, presents a feature which far surpasses that of any other structure of the kind. The dome has also its simplicity well preserved, by being clear of those pitiful small windows which disgrace St Peter's. A radical defect in St Paul's, is its having two orders in the height of the elevation, by which the simplicity and grandeur of the general effect are much diminished; but in the western façade, the upper and lower porticos, occupying a considerable proportion of the breadth, being also well isolated, and having a pediment enriched with sculptures extended over eight columns, produce, altogether, an imposing effect. The manner in which the turrets are constructed and finished, has little claim to commendation. The smallness and varied shape of the windows are objectionable. If there had been niches, with statues instead of windows, in the lower order, and the windows of the upper order made as large as the space would admit, and of uniform shape, the whole would have been more conformable to the character of a temple. We are aware, that this would have required a considerable change of the interior arrangement. The drawings we have given, will convey a distinct idea of the plan and elevation. For much of the interior we must refer to the building itself, and to the very masterly section made and published by Messrs Gwyn and Wale; but the following particulars, respecting the construction, cannot fail of being acceptible to the reader.

Taking down the old edifice.

"*Of the taking down the vast Ruins of the Old Cathedral, (St Paul's) and of the Foundations of the Old and New Structure.*—The pulling down the walls, being about 80 feet high, and five feet thick, was a great and troublesome work. The men stood above, and worked them down with pickaxes, whilst labourers below moved away the materials that fell, and dispersed them into heaps. The want of room made this way slow and dangerous, and some men lost their lives. The heaps grew steep and large, and yet this was to be done before the masons could begin to lay the foundations.

"The city having streets to pave anew, bought, from the rubbish, most of the stone called Kentish rag, which gave some room to dig and to lay foundations; which yet was not easy to perform with any exactness, but by this method:

"The surveyor placed scaffolds high enough to extend his lines over the heaps that lay in the way, and then by perpendiculars set out the places below, from the lines drawn with care upon the level plan of the scaffold.

"Thus he proceeded, gaining every day more room, till he came to the middle tower that bore the steeple. The remains of the tower being near 200 feet high, the labourers were afraid to work above, thereupon he concluded to facilitate this work by the use of gunpowder.

Used powder.

"He dug a hole of about four feet wide, down by the side of the north-west pillar of the tower, the four pillars of which were each about fourteen feet diameter. When he had dug to the foundation, he then, with crows and tools made on purpose, wrought a hole two feet square, level into the centre of the pillar. There he placed a little deal box, containing eighteen pounds of powder, and no more. A cane was fixed to the box, with a quick-match (as gunners call it) within the cane, which reached from the box to the ground above; and along the ground was laid a train of powder, with a match. After the mine was carefully closed up again, with stone and mortar, to the top of the ground, he then observed the effect of the blow.

"This little quantity of powder not only lifted up the whole angle of the tower, with two great arches that rested upon it, but also two adjoining arches of the aisles, and all above them; and this it seemed to do somewhat leisurely, cracking the walls to the top; lifting visibly the whole weight about nine inches, which suddenly jumping down, made a great heap of ruin in the place without scattering. It was half a minute before the heap, already fallen, opened in two or three places, and emitted some smoke. By this description may be observed the incredible force of powder: 18 pounds only of which lifted up above 3000 tons, and saved the work of 1000 labourers.

"The fall of so great a weight, from a height of 200 feet, gave a concussion to the ground, that the inhabitants round about took for an earthquake.

"Encouraged by this success, he thought to proceed this way; but being obliged to go out of town in the king's service, he left the management of another mine begun to the care of his next officer, who, too wise in his own conceit, put in a greater quantity of powder, and neither went low enough, nor sufficiently fortified the mouth of the mine; and though it had the effect, yet one stone was shot out to the opposite side of the church-yard, through an open window, into a room of a private house, where some women were sitting at work, without any harm done. This accident frightened the neighbours to that degree, that he was importuned to use no more powder, and was so directed also by his superiors; though, with due caution, it might have been executed without any hazard, and saved much time and money.

"He then turned his thoughts to another method, to gain time, prevent much expence, and the endangering of men's lives; and that was, to make an experiment of that ancient engine in war, the battering ram.

A strong mast as a battering ram.

"He took a strong mast, of about 40 feet long, arming the bigger end with a great spike of iron, fortified with bars along the mast, and ferrels. This mast, in two places, was hung up to one ring with strong tackle, and so suspended level to a triangle prop, such as they weigh great guns with. Thirty men, fifteen on a side, vibrated this machine to and again, and beat in one place against the wall the whole day. They believed it was to little purpose, not discerning any immediate effect. He bid them not despair, but proceed another day. On the second day, the wall was perceived to tremble at the top, and in a few hours it fell. The reason to be given for it may be this: It is not by any present violence the ram is able to overturn a wall of such bulk and compacture, but incessantly vibrating by equidistant pulses, it makes a small intestine motion through all the insensible parts of the wall, and by degrees loosens all the bond of the mortar, and moves every stone from its bed; and though not the hundredth part of an inch every blow, yet this motion, once begun, hath its effects more and more, till at length it is quite loose, and falls. He made good use of this machine in beating down all the lofty ruins, and pleased himself that he had recovered this notable engine, of so great service to the ancients in besieging of towns, though great guns have now put them out of use, as more expeditious, and requiring fewer men to manage.

Description of ground and foundations.

"It has been before observed, that the graves of several ages and fashions, in strata, or layers of earth, one above another, particularly at the north side of St Paul's, manifestly shewed a great antiquity from the British and Roman times, by the means whereof the ground had been raised. But, upon searching for the natural ground below these graves, the surveyor observed, that the foundation of the old church stood upon a layer of very close and hard pot earth; and concluded, that the same ground which had borne so weighty a building, might reasonably be trusted again. However, he had the curiosity to search farther, and accordingly dug wells in several places, and discerned this hard pot earth to be on the north side of the church-yard about six feet thick, and more, but thinner and thinner towards the south, till it was, upon the declining of the hill, scarce four feet. Still he searched lower, and found nothing but dry sand, mixed sometimes unequally, but loose, so that it would run through the fingers. He went on till he came to water and sand mixed with periwinkles and other sea shells: these were about the level of low water-mark. He continued boring till he came to hard beach; and still under that, till he came to the natural hard clay, which lies under the city and country, and Thames also, far and wide." Wren's *Parentalia*, p. 283, 284, 285.

"The sand hill at Paul's, in the time of the Roman colony, was about twelve feet lower than it now is; and the finer sand easier driving with the wind, lay uppermost, and the hard coat of pot earth might be thus made; for pot earth dissolved in water, and viewed by a microscope, is but impalpable fine sand, which with the fire will vitrify; and, of this earth upon the place, where those urns, sacrificing vessels, and other pottery ware, made, which, as before noted, were found here in great abundance, more especially towards the north east of the ground.

Bad ground met with in the north-east corner.

Pottery ware found.

A pit sunk to the level of the Thames.

A square pier built.

"In the progress of the works of the foundations, the surveyor met with one unexpected difficulty; he began to lay the foundations from the west end, and had proceeded successfully through the dome to the east end, where the brick earth bottom was yet very good; but as he went on to the north east corner, which was the last, and where nothing was expected to interrupt, he fell, in prosecuting the design, upon a pit, where all the pot earth had been robbed by the potters of old time. Here were discovered quantities of urns, broken vessels, and pottery ware of divers sorts and shapes; how far this pit extended northward, there was no occasion to examine; no ox-skulls, horns of stags, and tusks of boars were found, to corroborate the accounts of Stow, Camden, and others, nor any foundations more eastward. If there was formerly any temple to Diana, he supposed it might have been within the walls of the colony, and more to the south. It was no little perplexity to fall into this pit at last. He wanted but six or seven feet to complete the design, and this fell in the very angle north east. He knew very well, that under the layer of pot earth, there was no other good ground to be found till he came to the low water mark of the Thames, at least forty feet lower. His artificers proposed to him to pile, which he refused, for though piles may last forever, when always in water, (otherwise London bridge would fall,) yet if they are driven through dry sand, though sometimes moist, they will rot. His endeavours were to build for eternity. He therefore sunk a pit of about eighteen feet square, wharfing up the sand with timber, till he came forty feet lower into water and sea shells, where there was a firm sea beach, which confirmed what was before asserted, that the sea had been in ages past, where now Paul's is; he bored through this beach till he came to the original clay; being then satisfied, he began from the beach, a square pier of solid good masonry, ten feet square, till he came within fifteen feet of the present ground, then he turned a short arch underground to the former foundation, which was broken off by the untoward accident of the pit. Thus this north east coin of the quire stands very firm, and, no doubt, will stand. This narrative may be of use to others not to trust piles, unless always, and in all parts, wet; for almost all sorts of timber under water will prove everlasting, but wet and dry will soon perish. The same cannot be said of iron, for that will decay under water: but this has been observed, in taking out cramps from stone work, at least 400 years old, which were so bedded in mortar, that all air was perfectly excluded. The iron appeared as fresh as from the forge. Therefore in cramping of stones, no iron should lie within nine inches of air, if possible; for the air is the menstruum that consumes all materials whatever. When there is a necessity to use iron for want of stones large enough, care is to be taken to exclude sufficiently the air from it. To mention another caution of use to artificers; some cornices of large projections, though the upper joints are as close fitted as good workmen can make them, yet in the melting of snow, the water will dribble through, and stain the cornice. The surveyor thus avoided this inconvenience; he caused the masons so to work the stone next the joint, as to leave half a quarter of an inch, rising on each side, that the water might sooner fall off, than soak to the joint; and this he observed in the paving of the upper portico of the principal front of St Paul's; besides, that the joints are run with lead: and the same is done, wherever he was obliged to cover with stone only." Pp. 285, 286.

Begun 1675, completed 1710.

"The first stone of this Basilica was laid in the year 1675, and the works carried on with such care and industry, that by the year 1685 the walls of the quire and side aisles were finished, with the circular north and south porticos; and the great pillars of the dome brought to the same height; and it pleased God in his mercy to bless the surveyor with health and length of days, and to enable him to complete the whole structure in the year 1710, to the glory of his most holy name, and promotion of his divine worship, the principal ornament of the imperial seat of this realm.

"The highest or last stone on the top of the lantern, was laid by the hands of the surveyor's son, Sir Christopher Wren, deputed by his father, in the presence of that excellent artificer Mr Strong, his son, and other free and accepted masons, chiefly employed in the execution of the work.

"Thus was this mighty fabric, the second church for grandeur in Europe, in the space of 35 years, begun and finished by one architect, and under one Bishop of London, Dr Henry Compton."

Description of St Paul's.

Dome.

The piers of the vestibule stand upon an octagonal plan. They have archivolts thrown over them, resting upon every two adjacent piers, and forming eight arcades. The spandrels are filled with spheric portions to the level of the summits of the archivolts, and there form a complete circle. Upon this an entablature is laid, and the projections, being protected at the outer edge by an iron railing, constitutes what is termed the *whispering gallery*. Above this, the cylindric wall is raised to the base, or springing of the dome. The dome is formed of eighteen inch brick-work, and has a course of long bricks inserted through its whole thickness at every five feet in height. It was turned upon a centre, laid without standards or supports from below, every story of this scaffolding being circular, and the ends of all the ledgers meeting as so many rings, and truly wrought, it supported itself. The exterior dome is constructed of oak timber, supported by timbers, which rest upon a brick cone, two bricks in thickness. This cone springs from the same base with the exterior dome, and supports the stone lantern or cupola, which is equal to 700 tons. This dome rises higher than a semicircle; and the sides of its section, which are struck from centres in the base line, would, if continued, meet in an angle in its axis. See CARPENTRY, Plate CXXIX. Fig. 8.

In order to render the dome, cone, and cupola or lantern secure, immediately under where the cone comes in contact with the extrados of the interior dome, a channel is cut in a curbing of Portland stone, in which is laid a double chain of iron, strongly linked together at every ten feet, and the whole channel filled with lead. There is a similar hooping behind the frieze of the pedestal, which supports the exterior dome; and also four others, at different heights, surround the cone which supports the cupola or lantern.

Dimensions.

The extreme length of this edifice is 530 feet; its breadth, exclusive of the two circular porches, 250 feet; and its height, from the pavement to the top of the cross, is 366 feet. Height of the central nave to the crown of the arch 85 feet. Height to the top of interior dome 218 feet. Diameter of ditto, at whispering gallery, 112 feet. Diameter of exterior dome 140 feet. The total expence is stated at £736,752; of which £126,000 was raised by contribution, £1000 a year was paid by the king, and the remainder was raised by a tax upon coals brought into the port of London.

Old St Paul's.

Old St Paul's Church was first built in the year 610. It was burnt down in 964, and rebuilt in 1240. The steeple was struck with lightning in 1443, and rebuilt in 1631. The whole was totally destroyed by the great fire in 1666.

St Stephen's, Walbrook.

Plate CLXXV. Fig. 1.

Of the other numerous churches erected during the restoration of the city of London, after the before mentioned great fire, under the direction of Sir C. Wren, we shall only select that of St Stephen's Walbrook, which stands near the Mansion-house. We have fixed upon this, on account of the variety of forms it exhibits, and the ingenuity and taste displayed in the arrangement and decorations. The ground-plan, as will be seen, (Plate CLXXV. Fig 1.) is a parallelogram, 75 feet in length, and 56 in breadth, which affords room for two rows of seats, with a passage along each wall and in the middle; and this is the space judged convenient for an English church, to enable an audience to hear the service, if distinctly performed. The columns are placed along the outer passages, so as also to form a parallelogram; but within these, at each end, two others are introduced, by which a column is placed upon each angle of an octagon. The entablature, supported by the columns, is upon a rectangular plan; but upon it, the archivolts, rising upon every two of the before mentioned inner columns, complete an octagon, as in Fig 2.; and between these archivolts, spheric spandrels, being carried up to the level of the top of them, form a circle, as in Fig 3. Over the top of the archivolts, a piece of plain wall is carried up, equal in breadth to the margins, which surround the pannels in the spheric spandrels. Upon the cornice, which is laid upon the top of this, rises a dome 44 feet diameter, and 22 feet high, upon the apex of which stands a small cupola. The dome is decorated with enriched sunk pannels. The ceiling, supported by the columns, is flat adjacent to each angle of the great parallelogram; but the roof is supported by groin arches, with archivolts springing from the top of the entablature, and both the soffits and faces of the archivolts are enriched. By the columns being raised upon pedestals, and being of the Corinthian order, they appear rather too diminutive for the support of the dome. If the whole light had been procured from the upper part, and if the face of the walls had been divided by pilasters, and the spaces between them filled with niches, paintings, and sculptured tombs, this beautiful and ingenious piece of architecture would have been rendered still more perfect.

Plate CLXXV. Fig. 2.

Fig. 3.

Dimensions of 51 *Parochial Churches of the City of London, erected according to the Designs, and under the care and conduct of Sir Christopher Wren, in room of those which were burnt and demolished by the great Fire in the Year* 1666; *together with other Churches built and repaired, and Public Buildings.*

"In the 9th year of the reign of Queen Anne, 1708, an act of Parliament passed to erect 50 new additional parish churches in the cities of London and Westminster. The surveyor, being appointed one of the commissioners for carrying on the works, attended that service with all the application his other offices would permit; and preparatory thereunto, took occasion to impart his thoughts to this effect, in a letter to a friend in that commission." *Parentalia*, pp. 309—318.

General observations.

"The capacity and dimensions of the new churches may be determined by a calculation. It is, as I take it, pretty certain, that the number of inhabitants, for whom the churches are provided, are 5 times as many as those in the city who were burnt out, and probably more than 400,000 grown persons that should come to church, for whom these 50 churches are to be provided, (besides some chapels already built, though too small to be made parochial.) Now, if the churches could hold each 2000, it would yet be very short of the necessary supply. The churches therefore must be large; but still, in our reformed religion, it should seem vain to make a parish church larger, than that all who are present can both hear and see. The Romanists, indeed, may build larger churches; it is enough if they hear the murmur of the mass, and see the elevation of the host; but ours are to be fitted for auditories. I can hardly think it practicable to make a single room so capacious, with pews and galleries, as to hold above 2000 persons, and all to hear the service, and both to hear distinctly and see the preacher. I endeavoured to effect this in building the parish church of St James's, Westminster, which, I presume, is the most capacious with these qualifications that hath yet been built; and yet at a solemn time, when the church was much crowded, I could not discern from a gallery that 2000 were present. In this church I mention, though very broad, and the middle nave arched up, yet as there are no walls of a second order, nor lanterns, nor buttresses, but the whole roof rests upon the pillars, as do also the galleries, I think it may be found beautiful and convenient, and, as such, the cheapest of any form I could invent.

"Concerning the placing of the pulpit, I shall observe,—a moderate voice may be heard 50 feet distant before the preacher, 30 feet on each side, and 20 behind the pulpit, and not this unless the pronunciation be distinct and equal, without losing the voice at the last word of the sentence, which is commonly emphatical, and, if obscured, spoils the whole sense. A Frenchman is heard further than an English preacher, because he raises his voice, and not sinks his last words. I mention this as an insufferable fault in the pronunciation of some of our otherwise excellent preachers, which schoolmasters might correct in the young as a vicious pronunciation, and not as the Roman orators spoke; for the principal verb is in Latin usually the last word, and, if that be lost, what becomes of the sentence?

"By what I have said, it may be thought reasonable, that the new church be at least 60 feet broad, and 90 feet long, besides a chancel at one end, and the belfry and portico at the other. These proportions may be varied; but to build more room than that every person may conveniently hear and see, is to create noise and confusion. A church should not be filled with pews, but that the poor may have room to sit and stand in the alleys, for to them equally is the gospel preached. It were to be wished there were to be no pews but benches; but there is no stemming the tide of profit, and the advantage of pew-keepers." Pp. 320, 321.

Having given an account of sundry churches in the metropolis, we shall now describe one lately erected in a small provincial town, and another in a country village, from both designs made by Mr Telford. The former

Bridgenorth church.

stands within the precincts of the old castle of Bridgenorth in Shropshire. It was completed in 1796. The extreme length over the walls is 121 feet, the breadth 67; the height of the side walls, including the plinth upon which the order stands, and exclusive of the parapet, is 36 feet 6 inches. The height of the tower is 114 feet. The plan and elevation will be seen in Plate CLXXVI. From these it will appear, that externally a Tuscan order is continued round the fabric, and that, excepting two columns at the entrance, it is composed of pilasters. There is a pediment at each end, and a parapet in every other place. In the body of the church there are no breaks; those near the extremities are made to distinguish the several parts of the edifice; also by dividing the length, the elevation acquires some appearance of loftiness, and some resemblance of the ancient porticos is thereby obtained. The Tuscan order, besides being the most economical, has, when constructed of this magnitude, an air of majestic gravity; it is also in due subordination to the decorations of the outside of the superior part of the tower, and the interior of the church. There is only one row of windows 21 feet 3 inches high. In the tower, the belfry story has the Doric order in strong relief, and its entablature is carried along each face without any break. Over this is the apartment for the clock, and the whole is covered with a dome.

Plate CLXXVI. Description of outside.

Interior.

Internally, the body of the church is a parallelogram 77 × 60 feet; the middle aisle is 29 feet 9 inches in height from the pavement to the ceiling. The side aisles 27 feet. Six Ionic columns are placed along each side of the middle aisle, and two of larger dimensions stand at the entrance into the chancel, so that the full Ionic entablature is continued quite round the middle aisle. The chancel is square, and, to render it more solemn, is lighted from the top. This also makes room for paintings or statuary over the altar, and on each side of it. On one side of the chancel is a vestry room for the clergyman, on the other side is one for the parish officers. The church is sufficiently lighted by the three large windows on each side. Originally, there was only a narrow gallery at the entrance end for the singers; but some years after the church was completed, in order to obtain more pews, a gallery was erected along each side. On each side of the circular entrance lobby, are stairs which communicate with the galleries. The space contained in the body of the church corresponds to that recommended by Sir C. Wren, as the maximum for an audience hearing distinctly, viz. 50 feet in front, 30 on each side, and 20 behind the speaker.

Plate CLXXVI. Churches in the villages of Madely and Dawley.

Plate CLXXVI. is the plan of a church for the village of Madely, near Coalbrookdale, in the county of Salop. It was with some slight changes erected there, and a similar one at the adjacent parish of Dawley. Galleries being here considered absolutely necessary, the design was made with the view of forming and lighting the body of the church independent of them. For this puspose it was made 70 feet by 50, from which a space at each end of the four angles is cut off, to admit of large windows. From each of the longest sides there is a recess of 38 feet by 12, to contain galleries, &c. At the entrance end is a projection, to receive the bell tower, and, at the opposite end, is one for the chancel and two vestries. Externally, this arrangement affords great regularity of front in each direction. The dimensions being marked in the plan, every part will be evident by inspection. This church contains 1000 commodious sittings, besides what may be placed in the passages. The pulpit may be placed nearly in the middle of the chord line of a semicircle, which shall extend to the opposite sides, and being perhaps the most suitable of all positions.

Private dwellings.

Having seen the progress that the revived Roman architecture made in sacred edifices, we shall next endeavour to trace it in the private dwellings of different periods.

From a very well written account of the town of Shrewsbury, we have the following particulars respecting old English habitations.

Town houses.

The town houses of our forefathers, as far as they relate to the present subject, may be divided into the kernelled or embattled mansion, the hall or unembattled gentleman's house, and the tradesman's habitation. The embattled mansion partook both of the castellated and collegiate forms. Like the former, it was crowned with embrasures, and surrounded always in the country, and sometimes even in towns, with a moat, but had seldom more than one tower placed at the point of most strength, which consisted of three or four stories, containing on each floor a single room. These were doubtless built on the principles of the keeps of castles. Like colleges, the embattled houses were uniformly constructed round a quadrangle, with a turretted gate-house of entrance, though not fortified with the massive round towers and portcullis of the castle gate. The principal apartments were the hall, the great chamber, kitchen, and chapel. The hall was a copy of those in colleges, which in their turn were of conventual origin. Here the master, with his family and superior guests, dined every day at a long oak table, elevated on two or three steps called the high-dees at the upper end, whilst the tenants, and those of inferior rank, were seated at a table below, at right angles with the former. The hall was lighted with one or more Gothic windows, and a long bow window, forming a recess near the high table. It had no fire-place, but was warmed by a brazier of live coals in the middle, the smoke escaping from a hole in the top. This apartment being anciently always open to the roof, the timbers were formed into a pointed arch, carved and adorned with arms, rebusses, and quaterfoils. At the tower end was a wooden screen of latticed work, which supported a gallery for the minstrelsy on great days. Under it ran a narrow lobby with a passage through, which communicated with the buttery hatch, where the butler attended, to administer ale to the numerous applicants at all times of the day, and beyond these were the offices. The great chamber adjoined the hall at the upper end. In this apartment was the luxury of a fire place, if the wide open chimney-pieces of our ancestors deserve to be called luxuries, and it was the usual resort of the family when not at their meals. It is conceived also, that, as in the combination-room of colleges, and the locutorium, or parlour of monasteries, the master with his chief guests often retired soon after dinner from the cold atmosphere of the hall, to the social comfort of its hearth, while the inferior visitors were left to carouse by the dying embers of the brazier they had left.

The chapel was a small room often over the gateway, and sometimes adjoining it, and was rather an oratory for private devotion than for the assembling of a congregation.

Embattled mansion in the country.

To these ancient fortified houses succeeded the embattled mansion of Queen Elizabeth, or James I. This was of two kinds, the greater and the less; one an improvement upon the rude quadrangle, the other an expansion of the ancient castlet; one luminous and magnificent, with deep projecting bow windows, and the other lofty, square, and compact. Of the great square windows in such houses, it is a well known complaint of Lord Bacon, "that one knows not where to become to be out of the sun." The characteristic accompaniments of these houses within, were huge arched fire-places in their halls and kitchens; chimney-pieces in their chambers of state, richly carved, and adorned with armorial bearings, mixed with grotesque figures in wood, stone, or alabaster; raised hearths, long and massy tables of oak, from their bulk calculated to last for centuries. One apartment seldom omitted in houses of this rank and date, but never found in those of higher antiquity, was a long gallery for music and dancing, sometimes 150 feet long; a proof that the hall was now beginning to be deserted. At all events, the practice of dining in these great apartments at different tables, according to the rank of the guests, was scarcely continued below the Restoration.

Embattled mansion in towns.

The unembattled gentleman's house in towns partook of the general features of the above, but were of smaller dimensions, and without any fortifications. These were in general retired from the street by a small court, two or three sides of which were enclosed by the house and offices, the rest with walls, and shut up with a gate, usually without any lodge or apartment over it. The most ancient of such houses consisted of a thorough lobby, with a parlour beyond it on one side with a stone floor, the kitchen and offices on the other. The partitions were of rude oak, the chimnies wide and open, and the rooms, except the hall and great parlour, low and small. These comfortless habitations were succeeded by the houses of Queen Elizabeth's days. In them the original form was retained, though with considerable improvements. The entrance was by an enclosed projecting porch, which led to the hall. This was lighted generally by one great square window with cross mullions, a massy oak table beneath, at the lower end a gallery for music, or to connect the apartments above, and a fireplace, embracing in its ample space almost all the width of the room, the Christmas scene of rude and boisterous festivity; beyond was uniformly a parlour, and, on the other side, the great chamber, or withdrawing room, sometimes up three or four steps. In the windows of such houses, and those of a rank above them, are found the remains of painted glass, in a style which seems to have been fashionable in the seventeenth century; they consist of arms, cyphers, figures of animals, and scripture histories, or others in small round and oval pieces. Of these the drawing is extremely correct, but the colours faint and dingy, very unlike the deep and glowing tints of the foregoing centuries. These were probably of Flemish manufacture.

The tradesman's house.

The tradesman's house was one, or sometimes two long ranges united, terminating with gables in the street. The shop occupied the whole breadth next the street, and was entirely without glass, like our present unsightly butchers shops. Behind was a kitchen, and beyond a small open yard, round which were the warehouses and offices. The pride of the owners were their signs, which denoted the trade or craft by some animal or device. These either projected far into the street from the house, or were stuck upon high timbers opposite the door. In former days, our towns must have exhibited the appearance of the streets of Pekin, rather than of the open and lively air of a modern European city. The barber's solitary pole, and here and there a heavy gilt sign, projecting from an inn in an old town, are the only remains of these clumsy and inconvenient ornaments.

Longleate.

Amongst the earliest houses on the Italian model in England, was the princely mansion of Longleate, in Wiltshire, the seat of the marquis of Weymouth; it was built from the designs of Hans Holbein, in the reign of Edward VI. The plan and elevation may be seen in Plate CLXXVIII. It surrounds three sides of a parallelogram, measuring externally 220 feet from east to west, and 175 feet from north to south. The height is divided into three stories, the lowest has Doric pilasters, &c. the middle Ionic, and the upper Corinthian. In the south or principal front, in the lower story, there are sixteen windows and a door; in each of the other stories of this front are seventeen windows; the size of the lower ones is 9 feet × 4 feet 6 inches; of the middle 10 feet × 4 feet 6 inches; and the upper 7 feet × 4 feet 6 inches. They are each surrounded by a plain slender architrave, and some have tablets and small trusses under the belt which forms their sills, and this belt also forms the cap of the pedestal of the order. There is a parapet and balusters along the top of the front; there are also three small cupolas. The entrance door-way has a Doric column and pilaster on each side of it; over these is an open pediment with arms in the open parts. In this south front, near each extremity, there are two square projections, each occupying 21 feet in length, and separated by about an equal distance; on the east and west sides, are three similar projections, and one at each extremity of the northern side.

Plate CLXXVIII.

Description and dimension.

In the principal story, there is a hall 51 × 30 exclusive of the recess; an apartment on the right hand 42 × 30, exclusive of two recesses; one on the left 37 × 30, exclusive of one recess; the recesses are 17 × 8. Besides these, there is one apartment 30 × 25; one 27 × 23; a bedroom 24 × 23, ditto 31 × 22, ditto 23 × 22; a waiting room, at the entrance, 22 square; a chapel 47 × 22; and a staircase 27 × 21, besides others of inferior note.

Remarks.

From this specimen, it appears, that the school was imported in a very improved state; its external appearance having a perfect regularity, and being nearly free of tawdry ornaments, is evidence of correct taste, and great care in forming the design. By having a separate order for each story, the members are rendered very minute, but in a private dwelling, where several rows of windows are unavoidable, those slender proportions are more appropriate than in a public edifice. The upper windows are preserved of a good size. In the interior arrangement, the hall, and some of the principal rooms, have their uniformity destroyed by the recesses, and several of them are injured by thorough fares. What has here been described, applies to the house in its original state; but the whole interior has lately been renovated and improved, with much judgment and success, by Mr Jefferey Wyatt, and is now rendered a very superb habitation.

Inigo Jones.

Heriot's Hospital.

The next in succession, is the celebrated Inigo Jones, who about a century afterwards practised architecture extensively both in England and Scotland. In his magnificent edifice, **Heriot's Hospital**, (begun in 1628,) may be observed many features corresponding with some to be found in Longleate, only he has here been more profuse in sculptured ornaments about doors and windows, and has adhered more to the style of the baronial castle. Having formerly described this edifice pretty fully, we shall only here recommend attention to the mode of managing the chimney tops, which he has made of a polygonal shape, with concave sides. We have in another place already mentioned, that the operation of changing styles from Gothic to Roman, is very perceptible in some parts of this edifice.

Castle Ashby.

Castle Ashby, in Northamptonshire, was a work of the same architect, begun in 1642. It forms three sides of a square, whereof two sides consist each of three stories in height, while the one which unites them is only two stories. The two higher sides, like Longleate, are composed of the Doric, Ionic, and Corinthian orders. The two upper rows of windows are nearly of an equal size, the lower ones are smaller. This singular feature has a good effect. With regard to the interior, the apartments are too narrow for their lengths, thereby much resembling galleries: their being thorough fares is also very objectionable.

Wilton House.

WILTON, the seat of the Earl of Pembroke, was begun by Inigo Jones, in 1640. The garden front extends 194 feet. It consists of one row of large windows, with square attics over them, and small ones in the basement below: these latter have segment tops, and clumsy arch stones. All the other windows have architraves and flat entablature, except those in the turrets, which are at the extremities, which have pointed pediments over the principal windows. The turrets rise higher than the rest of the building, and have each a circular pediment over a window in this part. Between the turrets, an entablature with modillions passes unbroken. This, with the plain ground, or face of the building, has a good effect. Upon this entablature there is a parapet, with balusters, which hides the roof. The entrance door has coupled Ionic pilasters, with an arch like that over the middle of a Venetian window. On each side of this is a figure in a reclined posture, holding a small medallion of the family arms betwixt them. The plan, consisting of single apartments encompassing a court 105 × 95, renders the access inconvenient.

Description.

Dimensions.

The great dining room is 60 × 30 × 30; the ceiling is coved, the coved part plain, but the flat part is thrown into compartments twelve inches in depth, encompassed with enriched mouldings. A modillion cornice, with an enriched frieze, passes round the room; the architrave has only one member enriched; the whole depth of the entablature is three feet four inches, or $\frac{1}{6}$ of the upright part of the room. The pannelled dado occupies another $\frac{1}{6}$, and the remainder is thrown into pannels which have a full length figure painted in each, and between these pannels are heavy stucco ornaments. The cove occupies $\frac{1}{3}$ of the whole height, or ten feet. In the chimney piece the opening has an architrave round it, an enriched truss on each side, an entablature with a plain slab in the middle. On each side of this stands a full length figure, holding a cornucopia, &c. and behind these figures there are two small Corinthian pilasters; upon this entablature is an open scroll pediment, and the family arms, which reach to the great modillion cornice. The middle door, at the end, has Corinthian columns, an open pediment, and arms, &c. over it. This description will convey an idea of the manner adopted by this architect, in finishing a magnificent apartment.

Hopeton House.

About half a century afterwards, a similar progress was made in Scotland; for Hopeton House, on the bank of the Forth, was begun in 1698, from a design by Sir William Bruce. The main building consists of a low basement, and two stories; the two principal stories have their windows of nearly an equal height, the lower windows have a level cornice, the upper a narrow architrave only round them; the colonnade which unites the main building and wings is convex. The hall in the east front is 34 × 25, that to the west 28 × 25; there is one apartment 31 × 21, another 23 × 19; one bed-room 21 × 18, and an octagonal stair 18 × 16.

Melville House.

About the same time Melville house, the seat of the Earl of Leven, was erected by Mr James Smith, viz. in 1692. It consists of two principal stories, a basement, and attic; the two middle rows of windows are nearly of the same height, viz. 9 × 3.3 feet; the whole front is plain except belts between the windows, rustic quoins, and small Ionic columns, and a circular pediment over the entrance door; the roof is deep, with tall chimney tops; the hall or saloon 45 × 24, smaller ditto, besides stair, 24.6 × 17.6; staircase 26 × 24; two apartments 25 × 20; and two 22 × 20.

Chatsworth.

Description.

In 1681, Chatsworth, the seat of the Duke of Devonshire, in Derbyshire, was begun by Mr Talman. The western front is elevated upon a fine terrace, which is ornamented with a range of rusticated columns, having pannels between them, and protected on the top by an iron railing. The basement of the building is rusticated; there are four Ionic columns in the central part, and four pilasters on each side of them; these are 39 feet high, and include two stories; the windows are rectangular, but deformed with clumsy key-stones; there is a pediment upon the before mentioned columns; upon the entablature there is a high plinth and parapet, with balusters and vases. In the southern front the basement is rusticated; there are four Ionic pilasters at each extremity, but none in the middle; the windows are rectangular with clumsy key-stones. In the principal story, which is 18 feet high, there is a hall 74 × 30; a gallery 90 × 22; a library 50 × 25; another apartment 40 × 23; a bed-room 23 × 22; a chapel 50 × 26; and a staircase 30 × 22; the passages are 11 feet wide. The interior square which the buildings encompass is 96 × 75. From the size of these apartments it will be seen that this mansion is upon an extensive scale, and from the western front being elevated on so fine a terrace, its external appearance is magnificent and commanding. In works of great grandeur, a terrace, judicially managed, always confers dignity, and is, besides, the means of obtaining commodious access to the domestic offices in the lower story.

Dimensions.

Montague house, or British Museum, resembles a French palace.

Before we take leave of the 17th century, we shall give a short description of Montague-house, now the British Museum in London: Being on the model of a French palace, it is a specimen of the architecture then practised in that country. It was built in 1678, under the direction of Monsieur Pouget, a native of Marseilles, brought to England on purpose by the first Duke of Montague; the plan and elevation will be found in Plate CLXXXI. The buildings surround three sides of a court, which is 165 × 155 feet; on the side next the street is a high brick wall, having its external face worked in pannels, having also an entablature worked in brick; in the middle of its length is an arched gateway with Ionic pilasters and a pediment, standing between two small porters lodges, which project outward before the face of the wall; over this gateway is a cupola with a Saracenic dome; at the distance of 16 feet from the inside of this wall, a row of Ionic columns supports a roof and forms a portico, which reaches between the wings; these wings, on each side of the court, are composed of a range of narrow buildings one story high, which contain stables and various small apartments for domestics; on the right hand side is a carriage way from the court; towards the street these wings terminate in turrets rising above the outer wall, with deep curved roofs, ending in narrow points. The fourth side of the court is occupied by the main building, whose extreme length over the walls is 216 feet, its breadth 64 feet; along the whole length it is divided by a brick wall running nearly in the middle of its width; and, with the exception of the great staircase, the whole is subdivided by walls passing quite across in a right line between the outside walls, by that means forming the apartments on each side of the middle walls of nearly equal dimensions; the staircase, in its length, occupies the space of two apartments. Nothing can exceed the simplicity of this arrangement, but it unavoidably subjects all the apartments to be thoroughfares, which,

PLATE CLXXXI.

Description.

although suitable to its present destination, is by no means comfortable in a private dwelling. The great staircase is spacious, and decorated with large historical paintings by Charles de la Fosse, who is considered one of the best colourists in the French school. The landscapes are by James Rosseau.

Dimensions.

The hall is 35 × 27 feet; stairs 52 × 25; apartment opposite entrance hall 35 × 28; two others 30 × 28; four others 26 × 24; and two 24 square; the length of the front or entrance stair is 34 feet; it rises the height of the basement, which is 8 feet. The face of the main building has a break in the central part or projection, and another at each extremity; it has a rustic quoin at each angle; it consists of two stories, of which the upper windows are considerably the loftiest: They are rectangular and plain. The entrance door is rectangular with a flat cornice and deep frieze; the entablature along the top of the walls is heavy, and has a very singular sort of trusses; the roof is deep, with Dormer windows, having pointed pediments; over the central break there is a parapet with balusters, and behind this there is a singular sort of heavy square dome, with the appearance of rustics at the angles.

Sir J. Vanbrugh.

The 18th century was opened by Sir John Vanbrugh, a man of bold and original genius, who, after having restored fresh life and reputation to the English stage, introduced into its architecture a style peculiarly novel and imposing. It is probable that the success of his dramatic pieces had inspired boldness, and created that fertility of invention so eminently displayed in his architectural works; and the number and wealth of his employers afforded, in the course of a few years, sufficient opportunities to exhibit splendid specimens of his skill; for, in 1713, we find him employed upon Kings Weston, in Gloucestershire; in 1714, upon Castle Howard in Yorkshire; in 1715, upon Blenheim in Oxfordshire; in 1718, upon Eastbury in Dorset; in 1721, upon Seaton Delaval in Northumberland; and in 1724, upon Grimsthorpe, in the county of Lincoln. We shall give a short account of each, and a Plate with a part of the plan and elevation of Blenheim.

Kings Weston.

Kings Weston consists, as was general in that age, of a large hall, passage, and stair, which occupy the central third part of the mansion; but the apartments are so arranged as each to be entered separately, a measure [illegible] L. D. H. [illegible] rather new. The hall is 36 × 29 × 30; there is one apartment 29 × 21; one 22 × 20; three 21 × 20; one 21 × 18; and the rooms in the upper story are of similar dimensions.

The front elevation extends 90 feet; the basement is low with small windows; upon this six Corinthian columns occupy the central part, including two stories in which the windows are of equal height. Over the entablature is an attic with windows; there is a large semicircle in the pediment; upon the attic is a parapet; over the extent of columns is a tall arcade finished with embrazures; exclusive of this arcade, the top of the front is a level line with vases; the roof is hid; the windows have flat segment tops, also plain dressings round them, and a small truss under each jamb and sill.

Castle Howard.

Castle Howard, including offices, exhibits a front extending 660 feet; it resembles Blenheim; but here the central part of the elevation is more predominant. The order is Doric in coupled pilasters, but they are too much disconnected by breaks, and omitting the triglyphs. In the garden front, the central part is occupied by Corinthian pilasters, reaching from the top of the basement to the top of the edifice, including two full stories with a pediment; over this are four pilasters, and a cupola with statues; on each side the central part, one story only is extended above the basement; but this affords room for one range of very fine windows being continued along the whole of this extensive front, and conveys an idea of this space being occupied by one suite of apartments. The basement is rusticated, but, including a high plinth, is not one half the height of the order. The architrave round the entrance door is rusticated: the windows are all arched; they have imposts and small architraves, but no clumsy arch-stones. Upon the whole, this garden front is simple and fine.

The hall is 40 × 34 feet; saloon 34 × 25; one apartment 27 × 22; one 30 × 20; one 30 × 25; one 25 × 20; rooms at extremities 40 × 15 exclusive of bows; the chapel 50 × 31; kitchen 33 × 29.

Eastbury.

Eastbury, the front of the main building, has a portico of eight rusticated Doric columns 35 feet high, standing upon a front stair, the steps of which are upwards of 50 feet long; the jambs of the windows are rusticated.

There are two halls, one 55 × 26; one 28 × 26; two great stairs 23 × 18; one apartment 44 × 22; one 26 × 22; one 24 × 22; one 28 × 22.

Seaton Delaval.

Seaton Delaval. The main building is of the castle sort, with turrets at the angles, and projections at the middle of the sides, but has Doric rusticated columns and a pediment, also Ionic columns in the other front; the face of the wall is plain. The lower row of windows have pediments; the other flat entablature all have architraves with small corbels under the window sills. There is a semicircle in the pediments in the centre, and Venetian windows in the turrets at the angles; each of these turrets have four large torus mouldings at its base.

Grimsthorpe.

Grimsthorpe is a quadrangle, encompassing a court 105 × 78 feet. The garden front has an elegant Corinthian portico standing upon a well-proportioned basement, it being only about one half the height of the order; the hall 57 × 38; at each end of it two rows of pillars divide off two great stairs; there are eight niches in the back wall. The apartments at each end of the hall is 35.8 × 27; the large room 55 × 25; two 28 × 27; one 27 × 25; one 23.7 × 25; one 26 × 24; one 24 × 20; two 24 × 18; two 20 square; the hall to the garden front 35 × 20; gallery in the same front 105 × 15.5, exclusive of a passage at each end and a recess 35 × 10 in the middle. This is an extensive and excellent plan; passages down each side prevent thoroughfares.

Blenheim.

General remarks.

But even these magnificent edifices are greatly surpassed by Blenheim, in which this able architect has created both a magnificent palace and a splendid triumphal trophy. It has been observed by a very able critic, (Knight on *Taste*, p. 227.) that even in chusing the situation, Vanbrugh has, with great judgment, selected the place where a splendid mansion will, in a picturesque scene, form the finest feature; wisely considering that it was not necessary that the finest views should be had immediately from the mansion, but rather by means of walks laid out on purpose.

Description.

The buildings occupy three sides of a square entrance court. The mansion stands upon one side; the kitchen court on another; the stable court on the third; and the fourth is open towards the water and great bridge. The ends of the building which forms one side of each of these courts, make a part of the general elevation; and this elevation altogether extends 490 feet. The whole extent over all the courts measures 850 feet. Not being

Plate CLXXIX.

able to convey a distinct idea of this elevation, or the arrangement of the apartments, in words, we must refer to (Plate CLXXIX.), where a particular representation will be found. In the central part of the entrance front, the Corinthian columns and pilasters, standing on a low basement, and rising to 40 feet in height, are magnificent features, and the varied ornamented outlines of the top are truly magical. If there is any defect in this singular elevation, it arises from the central part not having sufficient elevation and mass in proportion to those in the square and pyramidal turrets towards the extremities. In the garden front, the outlines are equally fine; and the long range of windows in the principal story, have a singularly good effect. The basement is in good proportion to the superstructure, but is injured by the small circular windows. In both fronts, all the porticoes have, very properly, pilasters at the extremities.

Dimensions.

The following are the dimensions of some of the apartments in the principal story: The great hall 55 × 44; saloon 44 × 35; principal stairs each 33 × 11; great gallery 183 × 21 at the narrowest part, and 28 at the broadest; the vestibule, including the bow, 41 × 18; anti-rooms each 32 × 25; drawing room 32 × 22; little dining-room 32 × 18; grand cabinet 26 × 26; bed-room 26 × 20.

General observations on Vanbrugh's architecture.

In the works of this able architect, we find the following fine features: extensive front stairs, low basements, orders rising each to the height of two lofty stories, upper windows of as great a height as those in the first story, and a varied and ornamented outline at the top of the edifice. He is singular in using pilasters at the extremity of porticoes and colonnades. In the latter they are most correctly placed, in the former we know of no classical architype; but in his great works, where strength and durability were apparently the principal objects, even this deviation appears defensible; in short, every external feature contributes to produce an imposing effect. Internally, at the same time that he has presented the means of exhibiting extensive suits of rooms, by connecting doorways, yet by the judicious arrangements of passages and staircases, he has generally obtained a separate access to each apartment. In the management of the detail, he has been accused of unnecessary clumsiness. In some cases, this criticism is certainly just, but we are to keep in mind, that the scale he worked on admits not of comparison with little things. He perhaps may, with more justice, be reckoned a mannerist: Blenheim seems never to have been absent from his mind when forming designs, for he is always gigantic, but also always bold and imposing.

Earl of Burlington.

About this time architecture in England received much encouragement, and was considerably improved by the indefatigable exertions and liberal patronage of the Earl of Burlington; we shall, therefore, in order to convey an idea of his taste, give some account of his town residence in Piccadilly, London, which, in 1717, was new modelled by him.

Burlington House, Piccadilly.

Description.

The court which the buildings encompass is 180 feet by 130. It is divided from the street by a high brick wall, in the middle of which is a magnificent arched gateway of the Doric order, ornamented by a peculiar sort of rusticated work. Immediately within this gateway, on each hand, is a circular Doric colonnade, which altogether makes a semicircle. The passage under these is 15 feet wide. The kitchen offices occupy the left hand side of the court; the stables the right. At each end of these ranges there are separate entrances, and a short arcade connects them with the main building. The middle part of the main building is 86 feet in length; at each extremity 25 feet projects 10 feet before the middle part. The whole length over the walls is 130 feet; the breadth at the extremities 66 feet; in the middle part 58 only.

Dimensions.

The hall is 30 × 20 feet; saloon 20 × 20; apartment right hand side of the latter 28 × 20; that on the left 20 × 18. In the division, next the left hand extremity, are two 20 × 20; one 20 × 13; one 18 × 15; the great staircase 24 × 21. In the right hand extreme division is the chapel 40 × 20. The kitchen is 31 × 18.

Remarks.

In the elevation, there is at bottom a plain plinth about 4 feet high, the top of which is the level of the first floor, and up to this level there is a front stair, the steps of which are 31 feet long; and as it is all without the face of the projections, at the extremities its landing forms a terrace between them. The face of the first story is rusticated, and, including the plain belt which passes along the top, is 15 feet in height; in this story the windows 8.3 × 4 are rectangular with three heavy key-stones in each lintel. Upon the before-mentioned belt course, rises the Ionic order, which, including the entablature, is 24 feet 6 inches high. In the central part of the building are 6 three quarters columns, upon each of which the entablature is broken. In each of the projections at the extremities, there are two couple of pilasters, without any breaks over them. Within this order there is one row of windows; those in the middle division are rectangular 9 × 4 with pediments, alternately pointed and circular. In each of the projecting divisions there is a Venetian window, arched in the middle. Upon the entablature, there is a parapet with balusters and small pedestals over the columns.

In the general disposition round the court, the colonnade within the gateway, as seen from the front of the main building, produces an elegant effect; but the kitchen is situated at a very inconvenient distance from the dining-room. In the main building, from the principal stair not being in the middle, the communications are incommodious, and its effect as a fine feature is lost. There is also too much thoroughfare, and the apartments are small. Externally, the front is generally well proportioned; the first story, which forms a basement for the order, is not too high, and the upper story being principal, corresponds with what we have frequently recommended. The windows should have been loftier, for there is too much dead wall over them; and not even statues on the top, is, in our opinion, a sufficient reason for breaking the entablature; for by so doing, the columns seem erected for this purpose alone, instead of being, as they ought, an essential part of the edifice. The assembly room at York, Lord Harrington's house at Petersham, the Duke of Richmond's at Whitehall, and General Wade's in Cork-street, were from his design.

Colin Campbell.

Wanstead.

During this period, Mr Colin Campbell also laboured with much zeal and perseverance. He published an account of many works performed by him: our limits will only permit us to notice Wanstead in Essex. This noble front extends 260 feet; the basement is well proportioned, being only 15 feet high. In the principal story is one row of very fine windows; they are rectangular, with pediments alternately circular and pointed. In the middle, there is a magnificent portico of eight Corinthian columns, three feet diameter, and a balustrade along the whole front. Internally, on the principal floor, there is a great hall 51 × 36 × 30; a saloon 30 × 30 × 30; two apartments 34 × 24; two 24 × 24; four 24 × 20; four 22 × 20; two 24 × 15; four 15 × 12. A library 34 × 24; and a chapel of the same dimensions. Many of those

Dimensions.

apartments are thoroughfares, particularly the library, which cannot be reached without passing through several rooms.

General observations.

Hitherto we have seen spacious porticos placed at an inconvenient distance from the ground; halls and saloons occupying a great proportion of the middle of the main building; most of the apartments rendered thoroughfares; ceilings thrown into deep compartments; walls covered with heavy tabernacle frames; and both these, and doors, windows, and chimnies, loaded with clumsy stucco ornaments: all this proves, that magnificence more than comfort or conveniency has been consulted. The imitation of the Italian arrangement and decoration seems also to have exclusively occupied the attention of the architect; but, having acquired a facility in the exercise of the art of imitation, the next step was to accommodate his works to the climate in which they were to be placed, and render them suitable to the wants and habits of the occupiers. This opened a new and extensive field for genius and taste, and the changeable disposition of a wealthy society afforded sufficient opportunities for introducing variety. We shall now give a short description of several mansions constructed in this improved style, and also adduce some engraved specimens.

Robert Adam. His style.

Amongst the earliest and most successful practitioners of this new mode, was Robert Adam: he discovered the impropriety of introducing into private dwellings the gigantic proportions and decorations of Roman temples; he noticed also the too rigid adherence to the Greek orders in all situations, however ill adapted; he endeavoured to correct these defects by introducing variety in his external façades, modelling pilasters, entablatures, sculptures, and other decorations to suit each particular work and situation. For the interior he introduced a greater variety of forms into his apartments, likewise light and gay finishings, as painted ceilings, slender mouldings, pilasters and friezes with light grotesque stucco and painted ornaments, and fanciful and delicate foliage. It cannot be denied, that he, in various instances, transgressed the limits of propriety; but is it surprising, that, immediately after having broken the trammels, he should not always confine himself within the strict boundary of correct taste? and it will be admitted that he is delicate and gay, even amidst a profusion of ornaments, many of which might have been spared; as at the entrance into the Adelphi, and the gate to Sion House.

Sion House. Dimensions.

Sion House, which Mr Adam, in 1762 began to fit up for the Duke of Northumberland, consists of a square of old buildings new modelled, within which he introduced a magnificent circular saloon. The external dimensions of the square, exclusive of the towers at the angles, are 163 × 140; the breadth over the walls of the entrance side is 38 feet; on the right hand side 28, on the left hand side 24, and the side opposite to the entrance 40 feet. The hall is 49.3 × 30, exclusive of a circular recess at one end, and a square one at the other; on the right hand of the hall is a square anti-room 39.4 × 26, with a peristyle of insulated columns; on the left hand is an anti-room of an elliptical shape, with $\frac{3}{4}$ columns attached to the walls. The buildings on the right hand side of the square are occupied by the great dining-room 62 × 22, including a semicircular recess at each end, divided off by columns, and a drawing-room 44.6 × 22. On the left hand side of the square there is a private eating room 32.6 × 28; a great staircase 29 × 20; a bedroom, anti-room, and dressing-room. One half of the breadth of the fourth side is occupied by a fine staircase, with private rooms for the Duke on each side of it; the other half is wholly occupied by a gallery 130 × 14.6, besides the towers at the angles, and a break in the middle. This last feature is purely in the stile of Spalatro. The saloon, which occupies the interior square, consists of two circles, the inner 50 feet, the outer one 70 in diameter; the inner is pierced by eight openings, each fitted with columns, and the piers with niches; the outer has four openings with columns, and the spaces between them are filled with niches and square recesses placed alternately, as in the Pantheon at Rome.—The exterior of this circular saloon being inscribed in a square, leaves four triangular courts, which are very convenient for affording light to the interior apartments of a great mass of building. The passage from the hall into this saloon, and from thence through well contrived entrances and a fine staircase into this extensive gallery, is certainly, for magnificence, as proper an arrangement as can be well imagined; and this is, in some measure, heightened by the irregularity of the floors which the architect found in the old buildings; but it is at the same time obvious, that for want of passages, the apartments are still too much thoroughfares; and judging from the plan in Mr Adam's book, there is some difficulty in conceiving by what means there is any communication between the great dining-room and the kitchen. Water closets are placed in different parts of this extensive plan; a conveniency unknown to the architects of former times. The delicacy of the interior finishings and furniture is equally novel in a British dwelling.

Observations.

Kenwood. Dimensions.

In 1767, Mr Adam was employed by the Earl of Mansfield, then chief justice of the King's Bench, to new model, and make additions to, his mansion at Kenwood. In this work the principle of thoroughfare apartments is abandoned, the hall is 31 × 21; great stair 27 × 14; the total length of the library is 61 feet, the square part part is 36 × 22: this last, which was wholly new, is a noble apartment; each end is formed into a semicircle, and filled with book cases; these ends being divided off by columns, leaves the middle in a square form. The entrance is through one of the circular ends: along one side of the square part, are three large windows; on the other side is the chimney, with an arched recess on each side of it: the ceiling is a plain trunk arch considerably below a semicircle. In the inside finishing of this room Mr Adam produced a specimen of what he wished to introduce into British mansions. The chimney, besides a delicately fluted architrave, has, on each side, a slender pilaster, richly ornamented in the pannels; an enriched tablet occupies the centre of the frieze; and on each side are a couple of sphinxes, with an altar between them: over the chimney is a large pannel, surrounded by an architrave similar to that of the chimney, and in it a portrait of Lord Mansfield, in his robes: the arched recesses have delicate ornaments very light and airy; a sofa stands in each. The book-cases are divided by enriched pilasters like those at the recesses, and over them, there are at each end pannels with suitable classical devices, represented by elegant figures in the Greek taste. The columns which divide off these book-cases, are fluted Corinthian, standing upon the floor, and with their entablature reaching to the springing of the arched ceiling. This entablature altogether does not exceed $1\frac{1}{5}$ diameter, the architrave occupies the $\frac{1}{5}$ only, and the frieze and cornice being $\frac{1}{2}$ diameter each; the frieze is enriched with lions and the heads of deer, in allusion to the family arms; the cornice has all the members except the corona enriched. The ceiling has first a bordering of honey suckles and similar flowers; the rest is distributed into delicate pannelling, diversified by square, oblong, circular and elliptical forms: in the middle of

Description of the library.

some of these are painted devices, in the other parts are stucco enrichments in the lightest grotesque style, and the whole was relieved by painting the grounds of the pannels and friezes; so that in this room the new mode was completely established.

External fronts.

Description.

Externally, the north or entrance front, extending 90 feet, has 40 feet in the middle occupied by a portico of four beautiful Ionic fluted columns, 28 feet 6 inches high, with a pediment, and at each extremity of this front there is a corresponding pilaster. This order standing immediately upon the ground, and reaching to the roof, has a proper character, that is utility. Within the portico, which is partly projecting, and partly recessed, there are only two rows of large windows, whereas on each side there are three rows of smaller ones. This arose from having an old building to work upon, but has the effect of destroying that monotony so frequent in large houses.

Remarks.

The south, or garden front, which, along with the main building, also includes the library on one side, and the green-house on the other, extends 240 feet. In the main building, upon a rusticated basement, 17 feet high, are placed ten pilasters, 21 feet high; six of these are in the middle, and two at each extremity of the main building; they are pannelled and ornamented with honeysuckles; over them are a frieze and cornice, which taken together, are little more than one diameter high; the frieze is ornamented with flutings and pateras; the cornice has every member, excepting the corona, enriched; this entablature appears too light for the order and edifice. An ornamented belt crowns the basement, and another divides the principal from the attic story, and there is, besides broad pannelling over the principal windows, enriched with what Mr Adam terms the flowing rainceau. If these last had been omitted, and the windows made loftier, the effect would have been improved. Along the library and green-house, which are only one story, there is a beautiful Ionic order, without any breaks in the entablature. In each of these buildings four columns occupy the middle space, and two pilasters each extremity, a mode worthy of attention. The order stands immediately upon the ground line, though it would have been preferable if there had been one course under it as a plinth. The entablature is $1\frac{3}{4}$ diameter high, it is enriched but not crowded, the whole is well proportioned, and would have been seldom equalled for simplicity of outline, if there had not been arches over each window, which mixes the Roman with the Greek architecture. The general effect of the whole edifice is also injured by the arched Venetian windows in the low part, which connects the main building and wings; and the whole of this façade, though fine, savours rather too much of the Dioclesian school.

We have been more minute in the details of this work, because, both externally and internally, it affords specimens of the architect's taste when left at full liberty, as, in this instance, he acknowledges it to have been.

Luton Park.

Plate CLXXX.

Dimensions.

In 1767, the Earl of Bute employed Mr Adam to make designs for a splendid mansion at Luton Park, in Bedfordshire; the whole of this work is, of course, original, and its principal or entrance front being singular for a private dwelling, we have selected it for engraving, as a specimen of the architect's best manner. We shall therefore refer to Plate CLXXX. and condense the description as much as possible. The entrance hall, which is forty feet diameter, pierced by four openings with columns, into recesses behind them, is altogether singularly fine; the saloon 64 × 24, appears to be too long, it seems, in this climate, to be space improperly lavished; the passage ten feet wide along the middle, renders the access to the apartments very commodious; the small courts are very convenient for affording light in a large building. The library, 143 feet long and 25 wide, besides recesses, is a magnificent suite of apartments; the dining room 43 × 25; drawing rooms 43 × 25, and 37 × 24; with the intervening anti or second drawing room 48 × 25; complete another suite of equal splendour; the stairs being each only 19 × 16, appear inferior to the size of the apartments, but there being one at each extremity of the middle passage, is a great conveniency. The principal floor is also well accommodated with water closets.

Remarks.

The principal front having no windows, except in the bows at the extremities, admits of a fine colonnade reaching between the bows, and this with the row of niches and statues, and large medallions over them, compose a façade seldom equalled even in public edifices. Here the colonnade, reaching from the ground to the roof, and having no break in the entablature, every member forms an essential part of the composition which apparently cannot be removed without involving the destruction of the edifice. We cannot, however, bring ourselves to admire the pateras which this architect so frequently plants upon his friezes; the windows in the bows want more height. The front to the park is very chaste, only the portico is unnecessarily confined upon too small a circle; the frieze is too gaudy, and the windows are too small.

Castle Coole.

Dimensions.

Plate CLXXX.

Remarks.

Of the still more modern mansions, which exhibit the prevailing modes in private dwellings, we shall select two examples of houses for noblemen, and two others on a smaller scale for country gentlemen. The first is a design of Mr James Wyatt, for Castle Coole, the seat of Viscount Belmore, in the county of Fermagh in Ireland. The main or central building is 115 feet in length, and 80 in depth; its middle part, in the entrance front, is occupied by a quadrangular hall 41 × 31; an elliptical saloon 36 × 30 extends to the opposite front; between them a passage, of eight feet in width, is divided from the hall by two whole and two semi-columns; on one side of the hall is a breakfast room, and on the other a library, each 36 × 24; on one side of the saloon is a dining and on the other a drawing room, each 36 × 24; between the drawing room and library is a very magnificent staircase 36 × 18, having its first flight of steps in the middle of the space; between the dining and breakfast room is a back stair 18 × 15, and a beaufitter 20 × 12 feet. On each side of the main building, the wings extend, nearly in a straight line with it, for 82 feet each; and they are each 52 feet in depth; on the entrance front immediately adjacent to each side of the main building, there is a green-house 52 × 15; behind these are passages seven feet six inches in width, and bed rooms and dressing rooms, each 21 × 20; also two water closets; the extremity of one wing is occupied by a nursery of three apartments, two 26 × 16, and one 18 × 12; the other extremity has a billiard room 26 × 16; a bed-room 26 × 16, and a dressing room 18 × 12. These apartments occupy the whole of the principal floor, (see Plate CLXXX.) In this design, for a nobleman, the apartments are upon a moderate scale, and are well disposed; the stairs are centrical; the bed-rooms and nursery are sufficiently retired; and the latter having a communication with the back stairs, relieves all the public apartments; the only matter not distinctly made out is the mode of lighting the passages. Externally in the entrance front, there being only four columns in the central portico, and these placed immediately against the pilasters, do not appear to form a feature sufficiently bold for the edifice. The colonnades of the green houses, and those in the extreme divisions of the wings with their accompanying niches, have a rich effect; there being four columns with two niches, and two square recesses at each end of the wings, that part is rendered sufficiently important; but the full columns being placed close to the walls, gives too much the effect of an unconnected screen. In the back front, the four columns placed upon the end of the elliptical saloon, seem upon too small a circle for Greek architecture. But, upon the whole, this building, both with regard to grandeur of effect and judicious arrangement, is well deserving the attention of the architectural student.

Roseneath.

Dimensions.

Plate CLXXXI.

Remarks.

The other example of a nobleman's house we have selected, is a design of Mr Joseph Bonomi, for Roseneath Castle, a seat of the Duke of Argyle, upon the banks of the river Clyde, nearly opposite to the town of Greenock. The whole length is 184 feet, the depth 66, besides projections of 11 feet in the central part of each front, the one square, the other circular, and each having before them an insulated portico. The chief peculiarities of this building are, its breadth being equally divided by a straight passage 11 feet 6 inches in width along the whole of its length, and having a driving way under the entrance portico. These circumstances render the arrangement simple and commodious. (See Plate CLXXXI.) The hall is 25 × 25; the vestibule 60.6 × 11.6; library 32.6 diameter, with two large circular recesses; dining-room 31.6 × 22; music-room 36 × 22; study 24 × 22; billiard-room 31.6 × 22; bed-chambers (upon this principal floor) 22 × 19.3; dressing-room 18.6 × 12, and 16 × 12. There are two water closets. The principal stair 32 × 12 has its access ill arranged, and is too confined. The back stair is placed inconveniently at one extremity of the passage. Externally, both fronts are decorated with columns, which produce a fine effect. The entrance portico consists of five columns, which would be an absurdity if the driving way was not designedly along the front, and under the portico. The front stair had better been straight than elliptical. This design displays originality of genius, and a disposition to simplify truly laudable.

Bowden Park.

Dimensions.

Remarks.

Of the smaller dwellings of country gentlemen, we may mention Bowden Park in Wiltshire, a seat of Barnard Dickenson, Esq. designed by Mr James Wyatt. The main building is only 70 × 57. The inferior buildings, containing the offices and a green-house 50 × 18, lie immediately behind, and encompass a small court. The entrance hall is elliptical 23 × 28, of which about 10 feet project before the line of the front. On one side of the hall is a dining-room, and on the other a drawing-room, each 30 × 20. Immediately behind it are a principal and back stair, a small lobby, and a china closet. A water closet projects from it into the court, but is entered from the staircase. The space occupied by the best stair (extension of the lobby 15 × 10 which is before it) is 22 × 15, of which the china closet occupies the space under the landing. The lobby or passage to the back stair and dining-room is 15 × 7. The back stair is 12 × 7. On one side of these stairs is a breakfast room, which looks from a circular end into the before-mentioned green-house; and on the other a library, each 20 × 20. The connection with the offices is by the back stair, into a passage which communicates with a butler's pantry 13 × 8, besides a closet, a housekeeper's room 18 × 15, with a store-room 12.6 × 8, and a pantry 12.6 × 6.6, a kitchen 21 × 18, with a scullery 18 × 8.6, a dairy 13 × 10, and a larder 10 × 6, a servants' hall 21 × 20, and a shoe-room 6 × 5. This appears to be an excellent house on a small scale, only the kitchen seems much too distant from the dining-room, and the servants' hall still more so from the entrance hall. Externally, we are rather surprised to find an architect of Mr Wyatt's acknowledged good taste, placing columns so frequently in the convexity of a circle, so narrow as that formed by the projection of the end of this entrance hall. The columns being carried up the whole height of the building, accords with our ideas of propriety.

Oxberton.

Dimensions.

Remarks.

The other instance of a moderate sized and very compact house, is exemplified in that of Oxberton in Nottinghamshire, designed by Mr William Wilkins for F. F. Foljambe, Esq. It occupies only a space 72 × 68, exclusive of a circular projection of a part of one side about 17 feet. The entrance hall is 20.6 × 16, on one side of which is a breakfast room 22 × 16, and, on the other, a cabinet for natural history 22 × 16. Immediately behind the hall are some small closets, and a small circular lobby 5.6 diameter. Beyond these is the principal stair 20 × 15.6. On one side of which is the drawing-room, with the before mentioned circular end, it is 36 × 24. On the other side is Mr Foljambe's dressing-room 22 × 14, and a passage 5 feet wide leading to the office. Behind these is a dining-room 30 × 22, and a library 28 × 19; also a passage between them 6 feet wide, leading to a small back porch. We are not in possession of the plan of the offices. This is an example of singularly compact arrangement, and proves the advantages derived by placing the stair in the middle of the house. We observe the want of a back stair. Externally, the whole is very plain, except a Doric portico of four columns 4 feet diameter, without bases, the shafts fluted to an edge. This portico occupies the whole height of the front, and being Greek Doric, appears two massive for so small a building.

Gladswood near Melrose.

In addition to these examples, we shall only mention an elegant small dwelling-house, which has lately been built by William Sibbald, Esq. on the north bank of the river Tweed, at a place called Gladswood, near Melrose in Scotland. The approach is so managed, that the entrance front has only the appearance of being one story high, and the public rooms and principal bed-rooms are upon the same floor; but the situation being on sloping ground, a space behind the house is cleared, so as to render the access to the domestic offices level and commodious. The front elevation is constructed with neatly cut and polished stone, and decorated with columns. This charming little villa stands on the external angle of a bend of the river, where the banks are singularly bold and well wooded. It commands a view of the town and abbey of Melrose in one direction, and also of the abbey of Dryburgh in another. The Cheviot Hills bound a distant prospect in front, while the north and east are protected by a chain of hills, and being immediately surrounded by well cultivated fields, and an excellent garden judiciously disposed, we consider this altogether as a perfect model for the villa of a small freeholder.

Conclusion.

We are convinced that the reader, who has attentively followed us through this discussion respecting private dwellings, will have a distinct knowledge of their progress since the revival of the arts. He will also admit, that sufficient specimens and explanations have been produced, to afford him a perfect conception of the present state and practice of the art, and that by means of the data here selected from the ablest masters, his own progress in designing and executing buildings will be much facilitated. We have placed before him the results of the experience of ages, and his own genius and reflection will enable him to proceed to a still higher degree of perfection.

City architecture. Bath.

A very excellent specimen of city architecture was displayed about the middle of last century by Mr Wood at Bath. The city at that time consisted of narrow streets and mean buildings. He commenced his operations, by covering the low grounds on the western bank of the river Avon with ranges of buildings, in a regular and elegant style of architecture. These were elevated about 18 feet above the level of the natural ground by artificial terraces raised on arches, and covered with smooth pavement, and were named Parades.

Parades.

That to the northward is 580 feet in length, and 52 in breadth.

Queen Square.

From these parades, after ascending the hill to the north-west of the old town, Mr Wood formed Queen Square, of houses upon a larger scale than those erected upon the parades, and more ornamented with Roman architecture. The upper or northern side of this square, consisting of pilasters, columns, and a pediment, and the other sides sufficiently varied, to avoid the dull monotony found in many modern improvements.

Circus.

Having by this step disentangled himself from the old town, he at some distance from the before mentioned square built a circus, 500 feet diameter, pierced by three spacious streets. Here he introduced a correct and very rich piece of Roman architecture. The houses being three stories above the level of the pavement, have their fronts ornamented by the three distinct orders of architecture, viz. the Doric, Ionic, and Corinthian, in coupled columns, having their entablatures passing along without any break, except where the façade is intercepted by the before-mentioned streets. The columns projecting before the face of the walls three-fourths of their diameters, they possess bold relief. The metopes of the Doric frieze, and mutules of the cornice, are enriched. The friezes of the other two orders are plain, but an enriched foliage passes in a range between the Corinthian capitals. The whole presents a bold and rich piece of architecture, and from each of the three streets the spectator has, when entering, a fine crescent opposed to him. But we cannot help noticing as a defect the want of a pier, where these fine façades terminate at the angles of each street. If the several projections had been thus covered, these orders, instead of resembling a screen, would have been converted into an apparently essential part of the edifice, and the piers would have still formed a sufficiently distinct partition from the great plainness of the adjacent streets.

Crescent.

From this fine circus Mr Wood passed, by one of the before-mentioned streets, to a piece of ground which commands an extensive view of the valley, and there constructed a crescent extending 670 feet. This consists of a plain basement story, supporting a row of semi Ionic columns placed at equal distances, excepting in the centre, where there are two coupled columns on each side of an arched window, all the other windows being square and plain. There is no break in either the basement or entablature. At each extremity there is a return on the chord line of the crescent (or segment) for the extent of the width of the houses. Here at each angle there is a column, which had better been a pilaster; but as the order and columns are returned on the back part of the houses, and are there terminated by pilasters, which are continued, the whole is thereby rendered an essential part of the edifice, and not a screen. The appearance of the shafts of the large Ionic columns now quite plain, would be much improved by flutings. This crescent, which contains 80 houses, is one of the finest architectural features in England.

New rooms.

Having thus formed a new creation of splendid dwellings, the architect, for the accommodation of the inhabitants, constructed new assembly-rooms on a suitable scale, in a convenient situation, on the eastern side of the circus. The ball room, is 105 feet 8 inches long, 42 feet 8 inches broad, and 42 feet 6 inches high; the octagon room 47 feet diameter; the tea-room 66×41; and the card room 60×30.

Old rooms.

These rooms were opened in 1771; the lower assembly-rooms adjacent to the parade, had been established 21 years before that time.

Remarks.

From these great leading features, other streets, squares, and crescents, which, though inferior to those constructed by Mr Wood, yet by no means deficient in architectural merit, have since been spread along the face of the hill, and also on the eastern, or Bathwick side of the river Avon, rendering the city of Bath a suitable reception for the wealthy and luxurious.

General observations.

It would much exceed our bounds to include in this article, a full description and comparative statements respecting city architecture, as practised in different ages and countries. We shall therefore content ourselves with stating, that, in the cities of London and Glasgow, some excellent specimens may be seen, of extending improvements upon a nearly flat surface; and that at Edinburgh and Bristol an instructive variety will be found upon hilly ground. We may have an opportunity of again taking up this subject, and entering more into detail.

OF GOTHIC ARCHITECTURE.

Gothic architecture.

The attention to Gothic architecture having only been lately revived, the practice has not hitherto been digested into a like systematic order as that of the Greek or Roman; and it is not a little extraordinary, considering that, during the ages in which it was extensively practised, its operations were directed by men of science and literary habits, that no written rules have been discovered in the religious houses, which were then the only depositories of knowledge.

No written rules.

Observations by Mr Knight.

This has led Mr Knight, and other men of observation, to assert, that each architect proceeded independently of rules, and worked in the manner which to him appeared best calculated to produce a striking effect, and that it was in consequence of the absence of determined rules, that this school rose to the degree of sublimity it attained.

Denied by Dallaway, &c.

This is denied by other able and enlightened men, who have paid much attention to the subject, especially Dallaway, Milner, and Hawkins, who maintain, that although few arranged rules and proportions have been published in books, yet that the architects and workmen were constantly guided by known rules agreeable to the prevailing mode.

Gothic changes compared with Roman.

It is evident, although not so rigidly confined as the Egyptian, that the Gothic architects were fully as much limited as the Roman; for the contrast between the massy plain Norman style, and the latter or florid Gothic, is not greater than what was produced by varying from the plainness, simplicity, and oblong forms of the ancient Greek temples, to the circular, delicate, and highly ornamented edifices of the latter Roman.

Free-masons.

The non-existence of written rules may also be attributed to a jealousy in the fraternity of free-masons, who spread over Europe, and were the persons chiefly employed in constructing the Gothic churches; and these men, when constantly so employed from age to age, had no more need of written rules than many other men confined to one profession, and probably to separate branches of it. We may bring forward as an instance, the most expert of our British shipwrights.

We shall now consider the practice of Gothic architecture,

1. As regards the general distribution of the ground plan, and elevation of the edifice.
2. The forms of the essential parts.
3. The decorations.

General distribution.

1. The Gothic style having been employed almost exclusively in edifices appropriated to the purposes of the Christian religion, the outlines of the ground plan have almost uniformly been a cross. In the Greek and Roman oblong temples, the ratio of the length and breadth was determined by the number of columns placed at nearly equal distances along the ends and sides, while that of the height was regulated by the diameter of the column; but in the Gothic, where seldom any columns have been placed on the outside of the edifice, and the use of arches proving a relief from constraint within it, it is alleged, that the proportion of the length to the breadth has been determined by triangles and squares. Of this, Mr Hawkins, in his History of the Origin and Establishment of Gothic Architecture, (chap. x.) has produced an early instance from Cæsar Cæsarianus, a celebrated architect of Milan, who, in an elaborate commentary annexed to his translation of Vitruvius, (printed in 1521, a copy of which we have seen in the hands of Mr Taylor of Holborn,) has explained the principles of Gothic architecture. For a full dissertation upon this part of the subject, we must refer to Mr Hawkin's excellent book, and shall here only give two diagrams from Cæsar Cæsarianus, drawn upon the plan and elevation of the church of Milan, with his description of them, which, though not very distinct, will serve to convey an idea of the principles he means to inculcate.

Cæsar Cæsarianus.

Plate CLXV. Fig. 1.

Rules exemplified in the church at Milan.

Plan.

In Plate CLXV. Fig. 1. "the letters ABC, BCD, EFG. and FGH, are four equilateral triangles. IJK are the boundaries at the east end. JKL form an equilateral triangle, which touches the line that passes through the two eastern middle columns. These last, by their correspondence with the other columns, not only divide the body of the church from the aisles, but settle the foundation for the square tower in the middle, and show how it is constructed, the centre of which tower is the letter M. In like manner, the letters INO form the other equidistant line which passes through the two western middle columns, the measure of which line, from the south to the north door, is 128 cubits, (of 25 inches each.) The letters PQR are an equilateral triangle of the measure of 64 cubits, as are also, and of the like quantity, the letters STM. The letters UVW are an equilateral triangle, from the centre of one to that of another of the columns, which form the range extending towards the west, the distance of which columns is 32 cubits. Where the letters XUW are found, are the different indications for the smaller intercolumniations, which are of the measure of 16 cubits, from the centre of one to that of the other pillar; and the letters ZA shew the intercolumniation of the columns, between which they stand. They ascertain also the outside extreme width of the door of the vestibule in the front of the nave, and regulate the vaultings of the arches over that part, in the centre of which is placed the letter B."

Elevation.

With regard to the orthography or elevation, (Fig. 2.) "the triangle is here marked at the base with the letters ABCDEF, and the point of it is to be found at B; a perpendicular from which is dropped upon the base line, and there distinguished by the letter H. But in order," says he, "to show the method by which the colossal figure at the top was regulated, and those marks to have the rules for the largest triangle, I shall extend the before mentioned triangle on one side from A to I, being a space of 16 cubits; and from F to J on the other side. Drawing a line from I to J, I shall gain the length for raising two other lines, which form the equilateral triangle on the before mentioned perpendicular GH, at the point K, the extremity of the arch called in the third acute or pointed. This triangle, if placed upon the range of capitals of the smaller columns, marked L and M, will touch, at its extremity, the letter K. In like manner, if I place over the former a triangle on perpendicular lines, raised from A and F, the base of which will be NO, and its point P in the perpendicular PH, which forms the largest triangle QRP, I shall then have the base NO, resting upon the arch of the nave; which base, by touching the extreme line of the building, ascertains, with the letters ST, the place where the top of the border is to be; so do also the letters UV, a little distant from them, as to the border a little above. The letters XY give the base of a triangle on the capitals and upper vaulting; which upper vaulting is compacted together with an iron chain. Every vaulting of the arches is constructed by the compasses placed on an acute triangle, the strength of which, for supporting a weight, is always greatest at the top; but if the weight be placed a little on one side or other of the centre, the arch is easily broken. The method of placing an octagon tower on a square raised from the solid, is shewn by the letters UVW; and within the spaces LZ and MA is the range of lowest windows."

Dimensions.

The dimensions of this magnificent edifice are stated, on the authority of Carlo Torre, to be, from the modern front to the wall of the choir, more than 260 cubits, (of 25 inches), the length of the choir 60 cubits, and its width 28; the middle nave 32 cubits wide, and 85 high to the vaulting; the two side aisles next this nave are each 16 cubits wide and 60 high; and the two outermost aisles are each 16 cubits wide and 50 high. The vaulting of the Louvre is 130 cubits. It is supported by four columns larger than the others; upon these arches the cupola, which is octagonal, rests. This cupola is 202 cubits high from the ground. The columns or pillars are 52 in number, and, including the base and capital, each 46 cubits high, of which the base is 2 and the capital 10 cubits. These columns are each in girt 13 cubits, and the four columns under the cupola are 15 cubits girt at the capital and 22 at the base; they are clustered eight shafts in each.

Dome of Sienna.

Rules referred to.

Mr Hawkins, in the same chapter, (x.) likewise relates, upon the authority of Della Valle, his letters *Sensi*, vol. ii. that, in 1321, during the erection of the dome of Sienna, six architects were appointed to examine the work, who reported, as their opinion, that the new work should not proceed any farther, because, if completed as it had been begun, it would not have that measure in length, breadth, and height, which *the rules of a church require;* and, they farther added, that the old structure was so justly proportioned, and its members so well agreed with each other in breadth, length, and height, that if, in any part, an addition were made to it, under the pretence of reducing to the right measure of a church, the whole would be destroyed. Here *the rules for a church* are distinctly and repeatedly referred to, and must therefore have existed.

Willis on Abbeys.

Browne Willis, in the preface to his History of Abbeys, vol. ii. states, that in the most stately abbeys, the height was equal to the breadth of the body and side aisles; that the steeple and towers were frequently in height equal to the length of the whole fabric, or sometimes to the cross aisles from north to south, as in Bristol, Chester, St David's; that the cross aisles often extended half the length of the whole fabric, as did the nave or western part, that is, from the great door at the west end, to the lower great pillars which supported the steeple; that the side aisles are half the breadth and height of the nave. But the following dimensions of cathedral and conventual churches will better enable the reader to judge of the relative proportions of the great members of these sacred edifices.

Rules exemplified in York Cathedral.

In the cathedral of York the lengths of the nave and choir are determined by equilateral triangles, formed upon the whole extent of each side of the transepts, which terminate upon a line drawn across the face of the buttresses, at each end of the nave and choir.

Essential parts.

1st order.

2d order.

3d order.

With regard to the form of the *essential parts,* they are mostly defined in the following description of the three orders of architecture, as given by Dr Milner in his reply to Mr Whittington; the *first order* is characterised during its formation, that is to say, till near the latter end of the 12th century, chiefly by its acute arch (its pillars and other members being frequently Saxon,) but after its formation, not only by the narrowness and acuteness of its arch, but also by its detached slender shafts, its groining of simple intersecting ribs, its plain pediments without crockets or side pinnacles, and its windows, which were either destitute of mullions, or have only a simple bisecting mullion, with a single or triple trefoil, quatrefoil, or other flower, in the head of them. Of this order are the east end of Canterbury, the west end of Lincoln, and the whole of Salisbury cathedrals, besides the transepts of York Minster, and of Westminster Abbey. The *second order* is marked, not only by the fine turn of its perfect equilateral arch, but also by the cluster columns being, for the most part, formed each course out of the same stone; by the elegant, but not over crowded tracery of its windows and groining; by its crocketted pinnacles, tabernacles, and pediments, the latter of which, towards the conclusion of the fourteenth century, were made with an ogee sweep towards the arch they covered. To this order belong the nave of Westminster Abbey, the nave and choir of York Minster, the naves of Winchester, Exeter, and Canterbury cathedrals, Wykeham's two colleges, St Stephen's chapel, &c. The *third order* is known, not only by the flatness of the point of the arch, but also by its numerous, large, and low descending windows, together with the multiplicity and intricacy of its tracery; by its pendents from the roof; by the minuteness and profusion of its ornaments, both exteriorly and interiorly; by its fan-work and numerous shields and devices on the ceiling. To this order belong King's College chapel Cambridge, St George's chapel Windsor, and King Henry the VII's chapel Westminster.

Spires.

One of the finest features of Gothic architecture, and which, in many instances, still forms the most striking ornaments of our cities, is the tall tapering spire, which was first built of wood by the Normans, and afterwards in stone early in the 13th century. In the course of the 14th and 15th centuries, they were greatly increased in number. The following are the most noted.

	Height of tower.	Height of spire.	Total.	When built.
Old St Paul's	260	274	534	1221 of wood, and covered with lead.
Salisbury	207	193	400	1280 of stone.
Norwich			317	1361 ditto.
St Michael's, Coventry	136	164	300	1395 ditto.
Lowth, Lincolnshire	148	140	288	1516 ditto.
St Mary, Shrewsbury	76	140	216	1590 ditto.

St Alkmond, Salop.

Although the loftiness of these spires produces a very striking effect, yet it must be evident, to the most superficial observer, that much also depends upon the relative dimensions of the tower and spire. The following are taken from the church of St Alkmond, in the town of Shrewsbury, which, though not remarkable for magnitude, is reckoned, by persons of good taste, to possess singular elegance of form. The height of the tower, from the surface of the ground, is 70 feet, and it is 22 feet square on the outside; the height of the spire is 114 feet, and its diameter at the base 19 feet.

Foreign spires.

Inferior to the English.

On the Continent there are some also of great height; that at Vienna being 465, and at Strasburgh 456 feet; but in those, as well as at Rouen, Constance, and Bayeux, in France, from the diminution commencing at the base, the general outline has not the same degree of elegance as the English, which are elevated upon lofty square towers. Some of the latter are constructed with walls of incredible thinness, Salisbury spire being only seven inches. The finest effect is produced by spires whose outlines are quite plain, as those at Shrewsbury and Worcester. St Michael's at Coventry is hurt by sculpture.

Towers.

Many of the Gothic structures have very lofty square towers only, some highly decorated. The tower of the fine church at Boston in Lincolnshire, finished by an octagonal louvre, is 282; Lincoln 288; Ely 270; Canterbury 235; York 234; Gloucester 224; Durham 210; Beverly 198; St Nicholas, Newcastle-upon-Tyne, 194; Derby 174; Taunton 153; Doncaster 152; Radcliffe, Bristol, 148 feet in height.

On the Continent; the tower built at Florence by Giotto in 1334, is 264 feet, diameter 46; the falling tower of Pisa, 188; the center tower of St Owen at Rouen, which is octagonal, and built in 1309, is 240 feet.

Observations.

This variation in the style of ecclesiastical architecture, as it regards spires and towers, is very evident in different parts of England. In the counties of Northampton, Leicester, and Huntingdon, spires are found almost in every village. Whereas in the counties of Lincoln, Suffolk, and Somerset, towers generally prevail.

Of columns.

Rules for disposition.

In Gothic architecture, the columns, arches, some particular moulding and buttresses, are members which require to be noticed. With regard to the distribution of columns, it has been observed, that the rule, in our finest cathedrals, has been to divide the whole extent from north to south; that is, including the length of both transepts and the breadth of the choir, into ten parts; three of these parts or arches were given to each transept, one to each side aisle, and two to the nave or middle aisle; that the breadth of the side aisles determined the distance at which the columns were placed longitudinally. Perhaps the general mode of distribution may be explained in a still more simple way, by dividing the breadth of the nave into four, or, in some cases, as in the before-mentioned great church at Milan, into six equal parts; but, in order to obtain more free space, omitting the row of pillars which would, by this

Hint for pointed arches.

mode of division, have occupied the middle space, and which the use of arches enabled the architect to do without inconvenience. It may here be also, without impropriety, noticed, that attempting to make the narrow side arches as high as those over the middle space, may possibly have first suggested the idea of pointed arches.

General observations.

In respect to columns, conclusions have too generally been drawn, from considering the slender purbec marble columns (which are, in some instances, attached to a large central cylinder,) separately, or otherwise, by taking by itself each column of the great clustered pillar; and being thereby astonished at proportions in which the height is sometimes 120 diameters. But this is fallacious, because there ought, in a comparison of height with diameter, to be included the whole mass of which the pillar is composed, and from which the incumbent weight derives support; and when viewed in this manner, the pillars used in Gothic buildings will not much differ in the ratio of their height and diameter from those employed in the Roman architecture.

Rules for height.

In the cathedral of Milan, the height of the column is one-third of the whole extent across the edifice, at the transepts, viz. $\frac{138}{3} = 46$ cubits of 25 inches each; and this height is $7\frac{2}{3}$ diameter, of which the base and capital each occupied $\frac{1}{3}$ of a diameter. The four large columns in the Louvre were $6\frac{9}{11}$ diameter, of which the cap was $\frac{21}{100}$, and the base $\frac{8}{11}$ of a diameter.

Ratio between height and diameter.

Two pillars in Westminster Abbey were carefully measured by Batty Langley in 1742. They each consist of a large central cylinder, having four slender columns attached. The height of the central cylinder of one, which was erected in the time of Henry III. about 1240, is, including base and capital, five diameters of the whole cluster, and $7\frac{3}{7}$ of the central cylinder; the base is $\frac{7}{11}$, and the capital $\frac{1}{4}$ of a diameter. In the other, which was erected in the time of Edward I. the central cylinder, including base and capital, is five times the diameter of the whole cluster, and $8\frac{2}{11}$ times that of the central cylinder; the base and plinth is one diameter, the capital $\frac{1}{2}$ a diameter. These instances are sufficient to enable the student to pursue this mode of investigation, for which recent publications, respecting the English cathedrals, will afford sufficient data. We shall add another instance, which may lead him to consider this part of the subject in a still more important view.

Church of Toussaint at Angers.

In the church of Toussaint at Angers, a space, which is 63 feet in length and 31.6 in breadth within the walls, is vaulted by groin arching, of which the ribs are of a hard stone, cut and dressed. The interstices are filled with small rubble stone five inches in thickness. The arch over the middle space is 26 feet in height, the side arches each 13 feet. The whole of the central parts of this vault rest upon two columns, each 24 feet in height, and only eleven inches diameter. They stand in the middle of the breadth, and 15.6 distant from each end of the apartment. It is calculated, that the weight resting upon these columns is equal to 127,660 pounds. By experiments upon stone, similar to that with which the columns are constructed, each superficial inch carried 6650 pounds before it was crushed; but taking one half of this weight, the superficies of each column is 95 inches, the two 190; they should therefore support 632,750 pounds, or $4\frac{1}{2}$ times what they do. The walls of the apartment are $4\frac{1}{2}$ feet in thickness. Useful information may be derived from similar calculations upon English chapter-houses, supported by one or more columns. In the article BRIDGE, it has already been stated, that in the octagonal chapter-house at Elgin, the pillar bears more than 40,000 pounds upon every square foot, and when its roof was perfect the weight must have been considerably more. This middle pillar is 24 feet in height, and the ribs spring from each angle of the octagon.

Two very slender columns.

Calculations respecting the weight supported.

Elgin chapter-house.

Norman columns massive and decorated.

The Norman columns were generally even more massive than the Saxon had been. They sometimes consisted of a single shaft, cylindrical, hexagonal, or octagonal, not unfrequently fluted in a spiral direction, or embellished with lozenges or network in alto or bas relief, which rivalled the richest of the Palmyrean or Dioclesian pilasters. The body of the pier was sometimes a compound form, rectilinear or curvilinear, or having portions of columns upon two or more sides; and sometimes having two or more large columns joined together, with or without angular parts between them; or there was a large square or octagonal pier, with slender round columns at each angle. The capitals were plain, or a sort of volute, or consisted of flowers, leaves, shells, or heads of animals; and of these, varieties in the same row was not uncommon. These columns had scarcely any regular base, but rested on a plinth shaped to suit the shaft.

1st Gothic order.

The first deviation from the Norman was into 8, and soon afterwards, there was formed a central cylinder with slender shafts attached to it. These were divided in several parts of their height by small fillets; they rested on a common base, and were united under one capital, which was embellished with delicately sculptured leaves of the palm tree or other foliage, and frequently ornaments were carried up between the shafts.

2d Gothic order.

In the second great change or order, the central and attached columns were worked up together in various combinations as to number; the capitals were not much ornamented, but each column had a distinct one, consisting partly of plain mouldings, and partly of delicate foliage running round it.

3d Gothic order.

Little change took place in the columns, during the third or florid style of Gothic architecture.

Windows.

The *windows*, during the prevalence of the Norman style, were narrow and rounded on the top; two or even three were sometimes placed together, and they usually had columns at the sides, and sometimes were placed between them as mullions.

1st Order.

During the first change from the Norman, the windows were long, narrow, and lancet-shaped, divided by one plain mullion, and at most two in the upper tier; they had frequently a trefoil lozenge, or some simple ornament between the tops, and had small marble shafts on each side, both externally and internally. There were sometimes two or three tiers or rows of these windows in the east and west ends, and not unfrequently three in a row.

2d Order.

In the second æra, reckoned that of the most perfect Gothic, the windows were made much larger; they were divided into several lights, by mullions which spread into tracery of leaves, flowers, quatrefoils, rosettes, &c. in the upper part. During the time of the two first, and part of the third Edward, pediments were formed, at first by means of mouldings in straight lines meeting in an acute angle at a considerable distance above the top of the window, having crockets up the back of the mouldings, which terminated in a rich knot of flowers, resembling the blossoms of the Euphorbium. By degrees the mouldings of the pediment were formed into an ogee sweep, and elegant pinnacles were raised on each side at the springing of the arch; after expanding to a great breadth, the window was again considerably contracted.

3d Order.

In the third, or florid style, the windows become more open, and were flatter at the top; their parts were so minute as to become only a sort of frame for the glass, divided by rectilinear transoms, frequently ornamented by an embattled fret.

The *Ornaments* may be comprehended under the terms

Ornaments. Norman.

mouldings and sculpture. In the Norman style the mouldings were chevron work, or zig zag moulding; embattled frette; triangular frette; nail head moulding; billet moulding; or cylinder cut into parts; fascia, band or fillet; hatched mouldings; nebuli terminated by an undulating line. Ranges of small arches upon small pillars or pilasters were also used for ornaments; they frequently intersected each other, and were sometimes placed upon corbels or brackets with carved heads. These latter ornaments were likewise found in the spandrel of arches or capitals, and above the keystones. Some whole figures are found over doors in mezzo relievo, being the nearest approach made by the Normans to a statue.

1st Order.

In the first change from the Norman, the mouldings were less various than in the Norman, and were usually composed of leaves or flowers, with which, not only arches of windows, but pillars, were decorated. Trefoils, quatrefoils, cinquefoils, roses, mullets, bosses, pateræ, &c. are found in the spandrels of arches and above keystones. Ornamented pinnacles are found upon shrines; also pediments in straight lines, extremely high, with niches and small statues under them; and on the west front, niches with statues as large as life.

2d Order.

In the second order, the ornaments are more various and graceful: as finer niches, tabernacles, and statues; pinnacles though not so lofty, yet more richly embellished with leaves, crockets, and other sculpture; also rich screens, stalls, and panneled ceiling.

3d Order.

During the third order, there is found a profusion of fret work, figures, niches, tabernacles with canopies, pedestals, crockets, tracery; but above all the rich pendents and finials, all of the most exquisite execution, and that equally in stone, wood, and brass.

General distribution of ecclesiastical structures.

The following description of the situation and distribution of a religious establishment, during the prevalence of Gothic architecture, will convey a pretty distinct idea of the general plan of ecclesiastical structures. It is taken from a well written account of the town of Shrewsbury, published in 1808. The principal buildings of an abbey, were, 1st, The church, which consisted of a nave or great western aisle, choir, transept, and usually a large chapel beyond the choir dedicated to the Blessed Virgin, with smaller chapels or chantries adjoining the side aisles of the choir, and sometimes of the nave. In short, an abbey church differed hardly at all from one of our cathedrals. Attached to one side of the nave, commonly the southern, was, 2dly, The great cloister, which had two entrances to the church, at the eastern and western ends of the aisle of the nave, for the greater solemnity of processions; and over the western side of the cloister was, in general, 3dly, The dormitory of the monks; a long room divided into separate cells, each containing a bed, with a mat, blanket, and rug, also a desk and stool, occupied by a monk. This apartment had a door which opened immediately into the church, on account of midnight offices. Attached to the side of the cloister, opposite to the church, was, 4thly, The refectory where the monks dined. In the center of the upper end, raised on two or three steps, was a large crucifix. On the right hand, at a table, sat the abbot, when he dined there: and, in his absence, the prior with his guests, of which there were every day many; and on the left the sub-prior. The monks sat at tables, ranged on each side of the hall, according to their offices and seniority. Near the refectory, under which were cellars, as at Worcester, &c. was, 5thly, The locutorium or parlour, an apartment answering to the common room of a college, where, in the intervals of prayer and study, the monks sat and conversed. This was the only room in which a constant fire was allowed in winter. Beyond was the kitchen and its offices, and adjoining to it, the buttery, lavatory, &c. On the eastern side of the cloisters, was, in the center, 6thly, The chapter-house, where the business of the abbey was transacted. On one side was a place with stone benches around it, where, perhaps, the tenants waited; on the other, a room in which records were deposited, and near it the library and scriptorium, where the monks employed themselves in copying books. On this side also, close up to the transept of the church, was the treasury, where the costly plate and church ornaments were kept. Beyond the greater cloister was frequently, in the greater abbeys, a smaller, perhaps for the lay brothers, as at Gloucester. And more eastward was the lodging of the abbot, consisting of a complete house, with hall, chapel, &c. The other principal offices of the convent had also separate houses, viz. the cellarer or house-steward, the sacrist, almoner, &c. as at Worcester. In this part was usually the hostery and guesten-hall, rooms for the entertainment of strangers; also the apartments for novices. Westward of the cloister was an outward court, round which was the monks infirmary, and the almery. An embattled gate house led to this court, which was the principal entrance of the abbey. The whole was surrounded with an high wall, generally fortified with battlements and towers. The precinct which it included, was, besides the above-mentioned buildings, occupied by gardens, stables, a mill, barns, granary, &c. Some of the great abbeys situated in the country, as at Glastonbury and Furness, covered sixty acres.

Pluscardine priory.

In the survey of the province of Moray, in Scotland, we have the following particulars respecting the priory of Pluscardine, situated six miles west of Elgin, which, in the distribution of its internal buildings, is said to be after the plan of the French priories and convents of that æra. It was surrounded by a stone wall about 15 feet high, inclosing an area of ten acres. The first edifice is the church, originally intended to have been built in the form of a cross.

Dimensions of Pluscardine Priory.

Dimensions.

	Feet.	In.
Length from north to south, (on the east has been a suit of aisles,)	94	4½
Breadth within the aisles, ...	27	8
Ditto including the aisles, ...	46	10
Length of the eastern transept, ...	56	1
Breadth of ditto, ...	26	4
Contiguous to the church, on the south is the Lady or Virgin's aisle, extending from east to west, ...	56	1
Breadth of ditto, ...	13	0
To the south of the Lady's aisle is the chapter-house supported by a clustered pillar, an elegant room, having four very large windows, it is . . . . (square,)	30	0
Contiguous to this, on the south, is a vaulted lobby, leading to a cloistered court on the west.		
Beyond this, to the south, is the kitchen, supported by two pillars; length	45	6
Breadth	29	8

Beneath the southmost half of the kitchen was

	Feet.	In.
a large vault, employed as a cemetery; the doors to it are still to be seen.		
Contiguous to, and at right angles with the kitchen, on the west, was the refectory, a large hall; length	94	0
Beneath this there was a range of cellars.		
On the west of the Lady's aisle and chapter-house, &c. was a cloistered court, for enjoying the benefit of the open air in rainy weather; its south wall was formed by the north wall of the refectory; length	99	8
Breadth	94	4
Along the roofs of the Lady's aisle, and chapter-house, and kitchen, was the dormitory; length	114	2
Breadth	29	8

It was divided by a passage in the middle into two suits of bedchambers, in number thirteen.

At the south-east corner of the kitchen stood the prior's house, communicating with the church by a door in the south-east corner of the dormitory, the passage in the middle of which led by another door to the church.

Immediately above the east gate of the gable of the Lady's aisle was a chamber, in which the prior usually spent the forenoon.

Contiguous to the north side of the transept, and communicating with it by a door, was the vestry, a vaulted building, ... (square) 16 0

The garden was well stored with fruit trees, and a stream was conducted within the boundary wall, and drove a corn mill.

This priory was founded in 1230, by king Alexander II. The monks were Cistercians.

After the very full discussion respecting the progress of the Norman and Gothic styles, which we have already introduced into the heads of History and Practice, we shall be very succinct in the following references to the engraved specimens, for which we are indebted to the pencil of Mr Blore.

PLATE CLXVI. Fig. 1.

Plate CLXVI. Fig. 1. Crypt at Minstre, in the Isle of Thanet. Mr Flaxman states, on the authority of one of our ancient historians, that there was a monastery at this place, which was destroyed by the Danes in the year 600, and which was never afterwards rebuilt. It is therefore probable, that this crypt (which now forms the cellar of a farm house) was part of this early monastery. The style is very simple, and might with propriety be referred to an early date, without this additional circumstance in its favour.

Fig. 2.

Fig. 2. West door of the church of Cliff near Dover. This is a specimen of the early Norman style. The pediment over the semicircular door is decorated with the billett moulding, an ornament peculiar to this style. The keystone of the outer semicircular arch consists of a rude representation of the Deity in the act of benediction, and on each side is an angel. Within is a narrow border of semicircular interlacing arches; next to which is the embattled fret, another ornament also peculiar to this style. The innermost moulding is decorated with a series of flowers, in the execution of which there is no variety.

PLATE CLXVII. Fig. 1.

Plate CLXVII. Fig. 1. South entrance to the church of Jedburgh in Roxburghshire. The monastery of Jedburgh was founded by David I., consequently its age can be nearly ascertained. The north entrance is the latest Norman style. On the outside is the zig-zag, or chevron ornament, the most common of all the decorations used by the Normans. Next to this is a moulding, covered with a series of grotesque figures and flowers. The capitals of the columns are finished with foliage, and the columns themselves clustered.

Fig. 2.

Fig. 2. North front of the Abbey of Kelso, in Roxburghshire, also built by David I. In this, is an example of the interlacing of the circular arches, and in the large arch is a succession of mouldings well executed.

PLATE CLXVIII. Fig. 1.

Plate CLXVIII. Fig. 1. Arches from the Treasury, Canterbury. The capitals in this specimen are all varied, which is usually the case in all Norman works. Over each capital is an ornament, evidently copied from Roman remains. This an elegant specimen of the decorated Norman.

Fig 2.

Fig. 2. An arch from the tower of St Augustine's monastery, Canterbury, built immediately after the Conquest.

Fig. 3.

Fig. 3. An early specimen of the Catherine Wheel window, from the east end of Barfreston church, Kent. The whole of the east end of this church is in the latest Norman style, and highly decorated. The series of grotesque figures that surround the window are highly characteristic of the style.

Figs. 4, 5, 6, 7.

Figs. 4, 5, 6, 7. Specimens of ornamented columns from the tower of St Augustine's monastery, Canterbury.

Figs. 8, 9, 10.

Figs. 8, 9, 10. Norman capitals, the first from the tower of St Augustine, and the two last from the crypt under the cathedral, Canterbury. The last resembles very strongly an Egyptian capital which we have given from Denon, in Plate CL.

Figs. 11, 12.

Figs. 11, 12. Ornamental borders from Barfreston.

PLATE CLXIX.

Plate CLXIX. contains a view of the west front of Holyrood Chapel, Edinburgh, with the details of that period.

Holyrood House.

The Abbey of Holyrood House was founded and nobly endowed by King David I. in 1128. It suffered considerably when the English burned the palace in 1544, but it was soon after thoroughly repaired. Before the Restoration, it had been used as the parish church of the Canongate; but when the palace was repaired by King Charles, the chapel was fitted up in a very elegant manner, and was set apart as a chapel royal in all time coming. A throne was raised for the sovereign, and twelve stalls for the knights of the thistle, and a handsome organ was erected. As the roof of the chapel was in a ruinous condition, it was found necessary to repair it; but an injudicious architect who was employed, covered it with a new roof of flagstones, which the walls had not sufficient strength to support. Another architect reported in 1766, that the chapel would fall unless the new roof was taken off, and his prediction was verified on the 2d December 1768. The building is now completely in ruins, and the mullions of the fine Gothic window at the east end of the chapel are completely destroyed.

PLATE CLXX.

Plate CLXX. contains a representation of the outside and inside of Melrose Abbey.

Melrose Abbey.

The present abbey of Melrose, which stands on the south side of the Tweed, is justly reckoned one of the most magnificent in the kingdom, both from the height and embellishment of the columns, from the beauty of its sculptures, and the general symmetry of its parts. It was founded in 1136 by King David, endowed with large revenues and extensive privileges, and dedicated to the Virgin Mary.

"The church," says Mr Thomson, "is built in the form of St John's cross. The chancel, which is a very stately fabric, is still standing; its roof is very curious, and has much of the scripture history upon it. I have taken the measure of what is standing of this church, although much of the west part is so entirely demolished, that we cannot know how far it has reached in that direction. Its just length is 258 feet; breadth 137½; circumference about 943; height of the south window 24, breadth 16; height of the east window 34½, breadth 15½; height of the steeple 75; the spire gone. The east window, at which was the great altar, is a beautiful structure; consisting of four pillars or bars, with a great deal of curious work between them; and on each side, a great number of niches for statues. On the top, an old man with a globe in his left hand, resting on his knee, and a young man on his right; both in a sitting posture, with an open crown over their heads. On the north and south of this window, are two others of smaller dimensions. The niches are curiously carved, both the pedestals and canopies, and on which several figures of men and animals are curiously cut. On the south-east of this church are a great many musicians admirably cut, with much pleasantness and gaiety in their countenances, accompanied with their various instruments. Also nuns with their veils; some of whom are richly dressed. The south window is very much admired for its height and curious workmanship: Niches are on each side and above it, where have been statues of our Saviour and the apostles. Besides, there are many other figures on the east, or on the west side of this window: Monks curiously cut, with their beards, cowls, and beads: A cripple on the back of a blind man: Several animals cut very nicely, as boars, greyhounds, lions, monkies, and others. There are about 68 niches in whole standing: the statues were only demolished about the 1649.

So far with respect to the outside of the church. Within, on the north side of the cross, are beautiful pillars, and the sculpture as fresh as if it had been newly cut. On the west side is a statue of St Peter with a book open, his right hand on it, and two keys hanging on the left. On the south side of this statue, is that of St Paul with a sword. In the middle of the cross stood the steeple, a piece of noble architecture, a quarter of it yet standing, but the spire gone. The roof of the south side of the cross is still standing, where is a beautiful staircase, much admired by strangers, the roof of it winding like a snail cap. There was within the church a vast number of fonts curiously carved, and where were altars dedicated to various saints. In the portion of the church where worship is at present performed, are two rows of pillars of excellent workmanship, especially that to the south east, which, for the fineness of it, looks like Flander's lace.

With regard lastly, to what was in part, or altogether, separated from the body of the church, there was a cloyster on the north side, a part of the walls of which is still remaining; and where may be observed pleasant walks and seats, with a great deal of fine flowers nicely cut, as lilies, &c. also ferns, grapes, house-leeks, escalops, fir-cones, &c. The door at the north entry of the church is curiously embossed, and the foliage here, and in several places of the church, very beautiful. There were also here a vast many fine buildings within the convent, for the residence and service of the abbot and monks, with gardens and other conveniences; all this inclosed within a high wall, about a mile in circuit. Besides the high church, there has been a large fine chapel, where the manse now is, and another house adjoining to it, where the foundations of the pillars are still to be seen. On the north side of this house there has been a curious oratory or private chapel, the foundations of which have been discovered this year, and a large cistern of one stone, with a leaden pipe conveying the water to it." See the account of Melrose in the *Statistical Account of Scotland*, vol. ix. p. 89, by the Rev. Mr Thomson.

Plate CLXXI.

Plate CLXXI. contains a representation of one of the turrets of Henry VIIth's Chapel, and of a pendent from the cathedral church at Ely.

Private dwellings.

Ashridge.

Plate CXCI.

Hitherto we have considered Gothic architecture only in religious structures, but of late years, it has sometimes singly, but more frequently combined with castellated features, been employed in the decorations of private dwellings, viz. of the Earl of Bridgewater in Hertfordshire, the Earl of Moira in Leicestershire, the Earl of Grosvenor in Cheshire, and the Earl of Lonsdale in Westmoreland, all extensive and splendid mansions. With the permission of the noble owner, and aided by the able architect Mr Wyatt, we have selected specimens from the first of these edifices. We were induced to fix upon this, from its being constructed under the direction of a man of acknowledged fine taste, whose genius was left at free scope by a liberal and wealthy employer, and from its being situated within the reach of architectural students connected with the metropolis. In Plate CXCI. we have given the whole plan of the principal floor, in order to shew the relative situation of the parts, selected as specimens of Gothic decoration, and because the distribution, shape, and dimensions of the public apartments, are highly deserving of attention; nor is the merit less in the arrangement of the offices, which comprehend every conveniency in its proper form and place. The name and dimensions of each apartment being marked on the plan, the whole will be evident from inspection.

In the same Plate is given that part of the north front which is included between A and B on the plan. This, and a part of the south front from C to D on the plan, sufficiently shew the variety of manners in which the architect has managed the external façades. Our limits do not permit us to give a drawing of the chapel, which, both externally and internally, is of elegant and highly decorated Gothic, of the middle and latter styles. As it is professedly of rich cathedral architecture, it is on this account less appropriate to our present purpose, which is to treat of private dwellings.

Plate CXCII.

With regard to interior decoration, we have in Plate CXCII. given a section of the hall and principal staircase, from which it will be seen, that, in these apartments, the effects of the ornamental bracketted Norman roofing, richly canopied niches, with the numerous pannellings, small pillars, and pointed arches, are perhaps even more striking, than any application of Greek or Roman architecture. Similar observations will apply to the conservatory, in which the superiority of the Gothic is, if possible, still more evident.

We shall now conclude this branch of our subject, by giving a brief detail of the ingenious theory of Gothic architecture by Sir James Hall, Bart. which has already been noticed under the History of Architecture.

Sir James Hall's theory of Gothic architecture.

In Sir James Hall's theory, it is conceived, that the forms of Gothic architecture may have been derived from the imitation of a rustic dwelling constructed

Plate CLXXII. Fig. 1. Fig. 4.

as follows. Two rows of posts are thrust into the ground opposite to each other, the intervals between the posts of the same row being equal, and each post rising to the height of about three of those intervals, as shewn in the ground plan, Plate CLXXII. Fig. 1, and in the view, Fig. 4.

Elements of arcades. Fig. 2. Fig. 5. Fig. 2.

A set of slender rods of willow are then applied to the inside of each post, and thrust into the ground along with it. These rods being rather longer than the posts, they are bound together by two tyings, one near the ground, and the other about two-thirds of its height. The rods from that last binding upwards being entirely loose, and free to be moved in every direction. Fig. 2, shews the ground plan of this arrangement; and Fig. 5 one of the posts, with its rods applied, and as seen in front between the rows. In this simplest case, the number of rods applied to each middle post is 5, and 3 to each end post, as shewn in the ground plan, Fig. 2.

Fig. 3. Fig. 6. Fig. 8. Fig. 9. Fig. 7. Fig. 10.

The loose summits of the rods are then brought to meet, and are bound together, so as to form the frame work of a roof fit to bear the thatch, as shewn completed in the ground plan, Fig. 3; but in order to render the construction intelligible, the three different forms of which it is composed had better be considered separately. First, Two loose summits are made to meet from each pair of opposite posts, crossing each other in the middle, and producing the form of the Gothic pointed arch, a view of which is shewn in Fig. 6, the same being represented, or as executed with every such pair of opposite posts in the ground plan, Fig. 8. An horizontal rod or pole (which in this system is called the ridge-bar) is then laid upon the forks of the crossing rods, and bound to each of them, thus producing a continued Gothic arcade. Next two loose summits are made to meet from every neighbouring pair of posts in the same row, a set of arches similar to those first mentioned being thus produced, and standing opposite to each other in pairs, as shewn in Fig. 9, each pair of opposite arches being connected by a transverse ridge-bar laid upon the forks. Two loose summits now remain to be employed in each post. These are made to meet diagonally from the opposite corners of each rectangle; but in meeting, they are not made to cross as in the two cases last mentioned, but are applied side by side, so as to form a continued curve or semicircle, and are joined together after the manner of a hoop, as shewn in Fig. 7. These diagonal arches cross each other at the centre, as shown in Fig. 10, and at their crossing touch the underside of the ridge-bar.

Fig. 3. Fig. 11. Fig. 12.

These various forms will all be found combined in the ground plan, Fig. 3, and in the view, Fig. 11, seen as looking along from within. Fig. 12 shews a stone building of the Gothic style, in which all the same forms may easily be traced.

Elements of windows. Fig. 13. Fig. 14.

The mullions of the Gothic windows, seem to have arisen from the imitation of open ribs of cage-work. The simplest form is obtained, as shewn in Fig. 13, by a set of upright rods placed at equal intervals, split down to the level of the impost, one half of each rod being carried to the right, and the other half to the left, each forming an arch similar to a portion of the main arch, which it meets, and then by their crossing, producing a set of forms at once varied and symmetrical. Another design has been obtained, by splitting the rods, as in the last case, then bringing each half rod to meet with a similar half in the middle between each neighbouring pair of uprights, these halves at their meeting not being made to cross, but being bound back to back, and then drawn asunder, so as again to meet their own halves, to which they are bound, and so on till the space is filled, as shewn in Fig. 14, with a set of waving forms all perfectly equal and similar.

Figs. 15, 16.

These two last forms are represented as executed in stone work in Figs. 15 and 16.

In this manner, the rudiments of the Gothic style are pointed out by Sir James Hall in his memoir, read in the Royal Society of Edinburgh April 7, 1797.

The same gentleman has undertaken, in a work now in the press, to vindicate the authenticity of the principle here announced, by its application to the boundless diversity of forms employed in Gothic architecture, both as to roofs and windows, constructed according to devices similar to those just stated, and as affording an explanation of the other departments of the style equally diversified, as the door, steeple, pinnacle, border, &c. To this work the reader must be referred for more perfect information, which we have reason to expect it is well calculated to afford, having long occupied the unwearied research of the author, and being, we understand, illustrated by 58 beautiful engravings executed by Mr Blore.

If this system has really guided the Gothic architect, it seems strange, that the fact should not have been recorded in history; but Sir James Hall also undertakes to account for that silence in a satisfactory manner.

The following table of well established facts, translated from the work of a French author, Rondelet, being selected both from the Roman and Gothic schools, cannot fail of being acceptable to the young architect.

Table *shewing the ratio of the walls, and points of support of several Edifices, to the total superficies which they cover.*

Names of the Edifices.	Total superficies in		Superficies of the points of support in		Ratio in thousandths of the total superficies.

N. B. A Metre is equal to 39.371 English inches, and a Toise equal to 76.726 English inches.

Conclusion.

Conclusion.

Having discussed the history and practice of the various schools of architecture, and also endeavoured to develope the general principles on which the art is founded, we shall conclude the subject with a few general remarks.

Egyptian.

The ancient Egyptian architecture, from the simplicity of its outlines, and the locality of the subject of all its sculptures, appears to have a strong claim to originality.—That the works, in which it was displayed, were the offspring of superstition and despotism, is undeniable; that the surface of their edifices were the records of religious rites, astronomical knowledge, operations during war and peace, is likewise most evident; but their modes of sculpture having been distinctly defined, and stamped with a religious character, each effort became the act of a monastic community, and proved an effectual bar to any improvement arising from individual experience and competition. Although the remains of this school have, as historical monuments, deservedly enjoyed the admiration of mankind, yet being entirely local, and having been formed under circumstances not likely again to occur, few practical advantages can ever result from the study of its principles or practice. The experiment lately made in the front to the Museum in the street of Piccadily, in London, is a proof how unfit it is for private dwellings, or indeed for any purpose in these times, excepting perhaps a mausoleum.

Mode of moving large masses.

The removing and arranging large blocks of stone, of which many of the edifices were composed, has been adduced as an evidence of the great progress made by the Egyptians in practical mechanics; but as all their operations bespeak rather the patient application of labour than the efforts of genius, it is reasonable to conclude that the whole was accomplished by very simple means. The quarries being situated on the banks of the river Nile, enabled them, during its increase, to raise and remove, as far as its branches and canals extended, the largest blocks of stone which were required. The edifices being generally adjacent to the water, these blocks could be moved from the shore by means of strong frames, drawn as sledges, or upon rollers, and then raised into the situations for which they were destined, upon inclined planes of earth, which were afterwards removed.

India.

The religious edifices of India seem to have been constructed under circumstances somewhat similar to those in Upper Egypt, and, in respect to them, similar observations are applicable: They are, therefore, to the western world, also, more the subject of historical discussion than practical imitation. The utmost splendour we can trace in the descriptions of their ancient palaces, or those of the most enlightened of their Mahometan invaders, arose from the use of silks, feathers, and a profusion of gold, silver, and precious stones. These latter remarks are equally correct with regard to Persia, if we except Persepolis, and the works of the Greek and Roman invaders. With regard to Persepolis, we have formerly observed, that, from the slender proportions of the columns, it is probable their covering was slight; that the elementary parts of their capitals and bases, though partly Egyptian, might have been suggested partly by the rich silks, precious stones, and other decorations occasionally attached to the tops and bottoms of slender posts. Throughout Persia, in latter times, the use of Gothic arches, and Turkish domes, highly ornamented, have

Persia.

Conclusion.

been extensively introduced in their palaces, mosques, and tombs. The hand of the Mussulman has likewise reached the remotest quarters of India.

China.

In China, it is the repetition of tent architecture alone which is every where to be found; and, equally in the pagoda and palace, some additional japanning and gilding exhausts the limited resources prescribed by their mischievous legal regulations.

General observations.

From the eastward of the Euphrates and the Caspian, the architects of the West can, therefore, only glean some information respecting silks, feathers, gilding, japanning, and the slight, though sometimes elegant, forms of tent architecture; yet, even from this slender stock of materials, the man of genius will derive useful aids in the practice of his art.

Greece.

Three orders.

Specimens.

Columns should be large.

It was in the small and rugged country of Greece, that the arts, as well as the philosophy of Africa and Asia, were collected, refined, and exalted. Here architecture and sculpture, instead of deriving dignity, as formerly, from their magnitude, or from the mere application of an immense quantity of labour, became the subjects of original genius and keen competition: The ambition of surpassing each other in excellence, appears to have inspired not only individual artists, but whole states. Thus, from a few imperfect hints, probably imported into Greece, a totally distinct school was established, which has become the canon of the western world. The three Greek orders form a perfect gradation of character, and when preserved of due magnitude, and properly applied, never fail to command admiration; their friezes and pediments afford instances of the richest decoration that sculpture could supply; this was generally historical or allegorical, and composed of human, or other animal figures, of the most exquiste design and workmanship; it was only in the capitals of their columns, and the subordinate members of their entablatures, they introduced vegetable forms, and these were distributed with a peculiar delicacy. Our specimens of Greek architecture having been all procured from public buildings, seldom wholly covered on the top; we have, therefore, little knowledge of their mode of decorating ceilings; we know that the porches and walls of some of their temples were painted with historical subjects by their most eminent artists. Of the decoration of their doors and windows, little is known, and it does not appear they had any ballustrades. In their finest temples they worked with rich marbles; but the essential members of their orders represented the parts of a wooden edifice. In pursuing the practice of this school, the artist will find a sufficient variety in the specimens collected and published by Athenian Stuart, and in the Ionian Antiquities; and his own genius will have sufficient exercise in making a judicious selection, and in preserving the true spirit of the original, when adapted to local situations and purposes; and although our limits prevent us from pursuing this part of the subject further, yet we cannot quit it without remarking, that one of its finest members, a column, will seldom have much dignity unless of considerable magnitude, and therefore can only be introduced with success in edifices of more than usual consideration.

Roman school.

In the Roman school, the profusion of decoration which distinguished it, can only be considered as an injudicious extension of the Greek manner; and it has been remarked, that in their decorations they had more recourse to imitations of vegetables: But the distinguishing characteristic of Roman architecture was the circular forms, which, it seems probable, they originally derived from the Tuscans. The use of arches enabled them to cover spaces even larger than those formerly left open by the Greeks; this produced the beautiful temples of the Pantheon and of Vesta; by this means they were enabled to construct domes, and all the varieties of enriched soffits which furnished models for the most superb of our modern ceilings. They generally derived dignity from the magnitude of their orders, but they diminished it by placing them upon pedestals, instead of upon simple platforms in the manner of the Greeks. When to the beforementioned advantages, we have, in some future articles, an opportunity of adding their magnificent aqueducts and triumphal arches, it will be seen that a new and noble field was, by this people, opened to the architect and engineer.

Gothic.

In Gothic architecture, the ground plans were modelled indiscriminately upon the oblong platform of the Egyptians and Greeks, and the square and circular forms of the Roman school; but the universal application of groin arching, with the employment of materials of small dimensions, and a disposition to increase in comparative elevation, created a school very different from any that preceded it. The various modes which were from time to time adopted, to produce extraordinary effects, at last reduced the masonry of the edifice to the nature of a slender framing, and not unfrequently, in some parts, to resemble films of lace or filigree work. And although the minuteness of parts and profusion of decoration in the latter Gothic have exceeded the bounds of correct taste, yet even in these, and in every stage of this school, the discerning architect will find much to admire and to imitate: amidst such variety, he will be at no loss to select features suitable to most situations and circumstances, from the perfectly simple to the most highly embellished character.

General reflections.

In surveying each of the schools of architecture which have prevailed in the western world, it will be evident that the progress has hitherto uniformly been from massive plainness to an extreme of delicacy and a profusion of decoration. We hope that an attention to the general principles, here pointed out, may, in future, prove the means of preserving architecture from these blameable extremes.

Parts to be treated separately.

We are aware that the desire of rendering this article perfect, has extended it to an uncommon length, and yet we are conscious that many branches of this important art will still appear to have been almost overlooked; this renders it necessary for us to state, that having discussed the subject generally, it is our intention occasionally, during the progress of the work, to treat some of the particular parts at greater length, under their proper heads. See particularly MASONRY.

The following is a list of the writers upon architecture, who have been referred to in this article:

EGYPTIAN.—Pococke, Norden, Greaves, Volney, Granger, Savary, Denon, and French Commission of Arts.

INDIAN.—Robertson's Ancient India, Sir William Jones, Asiatic Researches, Maurice on Indian Antiquities, Grose, Daniel, Hodges, Col. Syme's Embassy.

PERSIAN.—Sir John Chardin, C. Le Brun, Macdonald Kinneir.

CHINESE.—Duhalde, Sir William Chambers, Le Compte, Lord Macartney's Embassy, Barrow's Travels.

GREEK.—Homer, Pausanias, Diod. Sicul., Strabo, Vitruvius, and from the latter author, we learn that Silenus wrote upon Doric symmetry; Theodorus, and on the Doric temple of Juno at Samos; Ctesiphon and Metagenes upon the Ionic temple of Diana at Ephesus; Philios or Pythius upon the Ionic temple of Minerva at

Conclusion.

Priene; Ictinus and Carpion upon the Doric temple of Minerva in the citadel at Athens; Philo upon the symmetry of sacred edifices; Hermogenes upon the pseudodipteral temple of Diana at Magnesia, and the monopteral temple of Bacchus at Teos; Argelius upon Corinthian symmetry, and the Ionic temple of Æsculapius at Tralles; also Nexaris, Theocydes, Demophiles, Pollio, Leonides, Selalanion, Melampus, Sarnacus, and Uphrana, wrote upon symmetry. Amongst the moderns, Pococke, Wheeler, and Spon, Chandler, Le Choiseul, Stuart, Willey Reveley, Revet, and Pars, have written respecting Greek edifices; and much information is also to be derived from the travels of Anacharsis. Of the ancient Romans, both the Plinys are good authorities; but Vitruvius is the only author professedly on the subject, whose works have reached modern times; and he only mentions two others who had preceded him, that is to say, Terentius Varro, who wrote one book, and Publius Septimus, who wrote two books upon architecture.

Since the revival of Roman architecture, the writers upon the art have been numerous, but the principal are the following:

Italians.—Leon Battista Alberti, Sebastian Serlio, Giacomo Barozzi, usually named Vignola, Andrea Palladio, Vincenzo Scammozzi, Piranesi. See particularly Eustace's *Classical Tour through Italy*. Lond. 1813.

French.—Philibert de Lorme, Blondel, Claude Perrault, Desgodetz, J. Rondelet.

British.—Sir Henry Wotton, Inigo Jones, Lord Burlington, Ware, Wren, Gibbs, Aldrich, Price, Chambers, Adam, Stuart; the Vitruvius Britannicus, begun by Campbell, carried on by Gandon, and lately continued to the present time, by G. Richardson. Although it does not fall within our plan to notice the numerous books of architectural designs, which have of late years made their appearance, we must not omit drawing the attention of the student to the valuable works of Mr Peter Nicholson, who has successfully applied the principles of geometry to the elementary parts of architecture, and shewn in what manner this art ought to be regulated by correct science. The writer of this article also here embraces the opportunity of acknowledging that gentleman's aid in what regards this part of the subject.

Gothic architecture has of late been ably investigated by Wharton, Grose, Bentham, Dallaway, Milner, Whittington, Britton, Carter, Dawkins, Sir James Hall, the Rev. J. C. Eustace, Mr Hawkins, Mr Haggit, and in various papers in the Archæologia.

For distinct and philosophical information respecting the principles of architecture, the reader is referred to Messrs Stewart, Alison, Gerard, and Knight, who have each written upon the subject of taste. (γ)

Civil law.

CIVIL LAW

CIVIL LAW, in a general sense, denotes the law of any particular state, more commonly called its municipal law; but, in a restricted and more usual sense, it signifies the legal institutions of ancient Rome, which are called by way of eminence *the* civil law.

The Roman laws, proceeding from a variety of sources, had, like the institutions of any other country which has for a considerable time been advancing in civilization, accumulated to a very great and inconvenient extent, when, in 438, Theodosius the younger, then emperor of the West, ordered a digest to be made; which, however, without exploring the other sources of the law, was confined to the institutions promulgated by the emperors, and then in force in his part of the empire. This *Theodosian code* was the first attempt at a methodical collection of the Roman jurisprudence, which had the sanction of public authority,—for several digests had been previously made by private lawyers, to facilitate the study and practical application of the law. But the most celebrated collection was that made about the year 533 at the command of Justinian, then emperor of the eastern empire. This collection, though posterior in time, did not supersede the authority of Theodosius's code, each being framed for the respective divisions of the empire over which these two emperors presided. So great, however, was the superiority of Justinian's collection, that, upon the dissolution of the empire, it came gradually to be adopted, more or less, even by those states of which the western division had been composed, and now forms part of the institutions of most of the modern states of Europe.

This celebrated collection consists, 1st, Of the *Institutes*, or elements of the Roman jurisprudence, intended as the rudiments of its study. 2d, Of the *Digests* or *Pandects* (πανδεκται) in 50 books, being selections from the writings of eminent lawyers systematically arranged. 3d, Of the *Code*, or a collection of the constitutions of the emperors in 12 books, brought down to a later period than the Theodosian code. And 4th, Of the *Novels*, or the *new* constitutions which had been promulgated from time to time by Justinian himself, the *Code* comprising only those of his predecessors. These different parts form together the body of Roman law known under the title of the *Corpus Juris Civilis*; the dicta of which, particularly of the institutes and pandects, being for the most part grounded in the true principles of a comprehensive utility, according with the moral sentiments of mankind, and expressed with great purity and elegance, have always been held in the highest estimation.

The revival of the Roman law in Europe, is commonly ascribed to the accidental discovery of a copy of the digests at Amalfi in Italy, about the year 1130. It is much more probable, however, that it emerged gradually into notice, not by any single accident of this kind, but with the gradual return of civilization which followed the long interval of barbarity, occasioned by the decline and final overthrow of the Roman greatness. Certain it is, that Justinian's collection, or the more valuable parts of it, whatever there may be in the fact of the discovery at Amalfi, were known and taught in some of the ecclesiastical seminaries in different quarters of Europe before that period.

The countries on the continent in which this system of jurisprudence has most authority, are Germany and Holland, where, unless when controuled by local customs, it forms the great body of their common law. In England it is received, under certain restrictions, in four species of courts, 1st, The courts of the archbishops and bishops and their derivative officers, usually called courts Christian, *curiæ Christianitatis*, or the ecclesiastical courts. 2d, The military courts. 3d, The courts of admiralty. And 4th, the courts of the two universities. In all these courts the authority of this law, and the different extent to which in different courts it may be pleaded, is grounded not on any authority in the law itself, but entirely on the custom or common law of the realm, corroborated as to the universities by act of parliament. In Scotland, its authority, where not contradicted by positive institutions, has been held by some lawyers as tantamount to the common law, and as, indeed, forming a part of it. That its authority, however, was at no time recognised to so great an extent, seems the more correct opinion; and it is certain that for at least a century, it has been recognised no farther than as supported by the express dicta, or analogies, of the decisions of the supreme court. Where these are silent, it may always, when not opposed by established custom or positive enactment, be pleaded as argument of grave consideration, but not as possessing any inherent and controuling authority. (s b.)

CIVITA-VECCHIA, the *Centum Cellæ* of the ancients, a seaport town of Italy, situated on a bay of the Mediterranean, on the arrondissement of Viterbo, and the department of Rome. It has a good harbour and arsenal, and was formerly the station of the pope's galleys. Not far from the town are the *Bagni dé Palazzi*, which are hot baths, known to the ancients under the name of *Aquæ Tauri*. There is also here a grotto from which sulphureous steam issues. About six miles from Civita Vecchia are the ruins of Leopolis, a town built by Pope Leo IV. in A. D. 854, and peopled with the inhabitants of *Centum Cellæ*.

Civita-Vecchia has always been considered as next to Ancona in maritime importance; and though the harbour is not capable of receiving large ships, it is frequented by numerous small vessels, which carry on a very extensive trade. The principal manufactures of this place, are those of leather, pottery ware, and linen and cotton cloths. Civita-Vecchia receives all the colonial goods which are consumed in the country, and carries on a considerable export and import trade. The principal exports are burnt sulphur, alum from Rome, grain, oils, wool, timber, salted anchovies, cheese, volcanic and red sand, which is used in making cement for building under water. The wood which is exported is principally staves of oak and chesnut, which are sent to Agde, Cette and Barcelona, and the alum was generally sent to Venice, France, and Holland. The imports are French wines, woollen and linen cloths, silks, salted fish, citrons, oranges, dry fruits, lint, soaps, and spices. Population in 1811, 9000 East Long. 11° 44′ 45″, and North Lat. 42° 5′ 24″. (w)

CLACKMANNAN, the county town of Clackmannanshire, is situated upon a bold swelling ground on the north side of the river Forth, about 22 miles above Leith. The name signifies the kirk town or village of Annan, from a connection formed in the 12th century betwixt the families of Bruce, and Annand of Annandale. The town is small and irregular: The buildings are humble, many of them going to decay, and are chiefly occupied by labourers, there being no manufactories of any kind carried on in it, excepting a few looms connected with Glasgow. Here the sheriff used to hold his courts, but the town-house and prison are in ruins, so that the courts are held at Alloa, except on particular occasions. At the west end of the town, and upon the brow of the hill, is situated Clackmannan tower, built prior to the year 1315, which was for a long period of years the favourite seat of the chief of the Bruces, who was hereditary sheriff of the county before the jurisdictions were abolished. The tower is rectangular, about 80 feet high; and from its elevated situation, forms a very picturesque, venerable, and strong feature in the surrounding scenery. Till lately there was a mansion-house of more modern date adjoining, in which a descendant of the line of Bruce lived, and who kept the sword and casque of the celebrated King Robert Bruce. These were bequeathed, with the genealogical tree of the family, to the Earl of Elgin, as representative of the family, in whose possession they are now to be seen. The view from the tower is esteemed amongst the finest in Scotland; the leading features of a beautiful landscape being there displayed in the happiest combination. From it the mazy course of the river Forth can be traced to a great distance, flowing through fertile fields, adorned with woods, cottages, towns, and vessels, while the horizon is formed by bold mountainous scenery, which, gradually receding from the view, blends with the western sky.

The population of the parish is estimated at 2800 souls, of whom 700 live in the town. N. Lat. 56° 15′, W. Long. 3° 40′. (r. d.)

CLACKMANNANSHIRE, a county in Scotland, situated on the north bank of the river Forth, bounded on the north by Perthshire, on the south by the river Forth, on the west by Perth and Stirling shires, and on the east by Fife and Perth shires; is about 10 miles in length, and 9 miles in breadth. It is one of the smallest counties in Scotland, and only returns a member to parliament alternately with Kinross-shire. It is divided into five parishes, viz. Clackmannan, Alloa, Tillycoultry, Dollar, and Logie; a part of the latter only is in this county.

As to its general aspect, the northern part is composed of that beautiful and picturesque range of mountains named the Ochills, which stretch in an east and west direction. They produce excellent sheep pasture. The western parts being rocky, are pastured by goats, on which account many persons in delicate health resort to Blair Logie in summer for the benefit of the goat milk. This spot has been denominated the *Montpellier* of Scotland; but the accommodation as to lodgings is very poor and humble indeed. The ground betwixt the Ochills and the sea is hill and dale, fit for the purposes of agriculture, with rich alluvial land on the banks of the Forth, termed carse ground. Besides the Forth, which bounds the county on the south, there are two rivers which flow through it, viz. the Devon, and Black Devon; these empty themselves into the Forth. The carse or alluvial land upon the banks of the Forth is very strong clay soil, and but little elevated above the level of the sea. The soil which immediately joins the carse upon the north is termed dryfield, and is of sandy loam, mixed with small stones. The hill and dale commences with the dryfield, and continues to the bottom of the Ochill mountains. The dryfield soil next the carse generally rests on a sandy bottom; but the greater part of the soil of the swelling grounds rests upon a strong tenacious red clay, mixed with sand and gravel, is quite impervious to water, and is denominated red till. The carse or alluvial land is of the best quality, producing luxuriant crops, and comparatively requires but little manure. The dryfield soil, which rests on a sandy bottom, is not inferior to the carse in point of produce; but the soil which rests upon the red clay is in value very inferior to any of the former, and requires much manure to keep it in good order for crops. In winter, it is liable to be excessively wet, as the subsoil will not absorb any of the superabundant moisture. The lower parts of the valleys are generally composed of a strong clay soil, but very different from the carse land. Upon the sides of the Devon, the soil is of a deep sandy loam, which bears good crops, and is termed haugh ground. There are a few inconsiderable patches of moss in the county where the lands are in cultivation; it however abounds upon the summit of the Ochills, which is much elevated above the level of the sea. The improvements in agriculture have been carried on here with great spirit. This county was amongst the first in Scotland where a farmer's club was instituted, patronized by the county gentlemen, with the present Lord Cathcart at their head. The first thrashing mill in Scotland was erected by the celebrated Mr Meikle in 1787, at Kilbagie, in the parish of Clackmannan; and this kind of machine is now to be found at almost every farm within the county. Attention has been paid in embanking considerable extents of land from the flowings of the sea, which have amply repaid the adventure. Lime is much used for land all over the county, though it costs very high, as the chief supply of it is either brought from Lord Elgin's works in Fife, or from the lime quarries in the vicinity of Dunbar.

Embanking.

Rivers.

River Forth.

With respect to rivers, the Forth, which flows upon the south side of the county, is navigable for ships of 500 tons as far up as Alloa; sloops of 60 tons can navigate to Stirling. The tides rise from 16 to 22 feet, and have the phenomena of double tides. (See the article ALLOA.) The banks and bed of this river are in general composed of soft mud or sleetch, which is daily brought down with the current, and gradually forms new ground. Opposite the Throsk is a ford, which is dry at low water, composed of large blocks of stone, chiefly of the kind termed greenstone. The mass of this species of rock nearest to this place is Stirling castle rock, and Abbey Craig, distant about four miles, from whence these stones must have originally come. Sand-stone rock appears at low water a little above the harbour of Alloa. There are salmon fishings on this river, but they are of very little value.

River Devon.

The river Devon takes its rise in the parish of Blackford, in the county of Perth, on the north side of the Ochill mountains. It runs eastward about 12 miles through the mountain glens, and then takes a sudden turn to the westward, at a place named the Crook of Devon, and keeps a western course till it falls into the Forth at the village of Cambus, immediately opposite to its source, which is only six miles distant in a north line. This river, after leaving the mountain district, flows through broken ground and rocks, which are chiefly of greenstone. These are worn into deep dark chasms, fearful to behold, and where the water is scarcely visible. One of these chasms is named the Deil's (Devil's) Mill, from an uncommon sound produced by the water very similar to that of machinery. Below this is the Rumbling Bridge, very narrow and without parapets, built across a narrow dark chasm, 90 feet deep; and further down the river is the Cauldron Lynn, where the water has scooped out the rock into the form of immense cauldrons, where it boils and foams without ceasing, and shews what strong effects even the attrition of water will produce. These objects are well worthy the attention of the naturalist, or the traveller of taste. This river, after dashing with impetuosity through rocky cliffs, at last flows placidly, in beautiful meanderings, through the picturesque and fertile valley of the Devon, till it joins the Forth. It is rendered classic by our poet Burns, who has styled it, *The clear winding Devon.* Through the valley the river flows upon a bottom of gravel, the banks being of a deep sandy loam, and towards the Forth they are of a strong clay. The tide flows only about half a mile up, where ships of small burden can enter.

River Black Devon.

The Black Devon is the only other river in the county. It rises among t the Saline hills in the county of Fife, passes north of the town of Clackmannan, and discharges itself immediately south from Clackmannan tower into the Forth. This river, from its source to its mouth, passes over strata of the independent coal formation, which is in many places exposed to view, and worthy the attention of the mineralogist. The tide only flows about a mile up this river, to a place named Parkmill.

Harbours.

The chief harbour and port in the county is Alloa, where there is excellent and safe accommodation for vessels. It has a customhouse, with a full appointment of officers; and as a port, comprehends Kincardine in the county of Perth, and Stirling, besides several intervening creeks on both sides of the river. At present, (1813) there are 10,000 tons of registered shipping belonging to the port, which are daily increasing. See ALLOA.

Mineralogy.

As to the minerals of the county, the rocks which compose them belong to two classes only, viz. the *transition*, and the *independent coal formation*. The Ochill mountains, which are on the north side of the county, are bold on the southern aspect, deeply indented (not rugged) in their horizontal line, with winding glens. *Bencleugh* is the highest of the range, being 2450 feet above the level of the sea, having a long flat summit or ridge. *Dun Myat*, or the *Hill of fair Prospect*, is 1345 feet above the level of the sea, and commands a most extensive and delightful view. The rocks which compose these mountains are of greenstone, flinty rock very splintry, basalt, amygdaloid, varieties of the trap class, petrosilex, and very coarse breccia, which latter composes the mass of rocks upon the western part of the mountains. Veins of lime-stone are found intersecting the hill strata. Beautiful agates (Scotch pebbles) are frequently found in the loose soil of the mountains; and also varieties of crystallized quartz, but of no value. Silver and copper have been wrought to a considerable extent in the Ochills. Lead and iron ore (hæmatites) have also been wrought on a small scale. Cobalt was found abundantly along with the silver, and ores of arsenic have also been occasionally found. These mining concerns have uniformly proved unsuccessful, and are now wholly abandoned, with considerable loss. In the veins, calcareous spar abounded, and barytes was found in large masses. The lead was wrought at Dollar, the silver and cobalt at Alva, the iron ore at Tillycoultry, and the copper at Blair-Logie and Airthry. There was a salt spring in the Airthry mines, but the kind of salt which impregnated the water was never tried. There is every reason to conclude, that these mountains abound with metallic veins. No mines or shafts have yet been driven under the level of the plain adjoining them.

Coal strata.

The strata of the coal field extends from the foot of the Ochills along the whole of the county, and are connected with the great coal field of Scotland. The coals found in this county are abundant, excellent, and valuable. The prevailing dip of the strata is to the north-east. The coal field is intersected with immense slips or dislocations of the strata, which have depressed the latter in some instances above 200 yards, forming distinct new fields of coal. Two main slips have been ascertained, and these run somewhat in a parallel line with the Ochills. Many diagonal slips have been discovered in working the coal of considerable extent, and a great number of small ones in every direction; still, however, the Clackmannanshire coal field is reckoned a clear field in comparison with other fields. Though the general dip of the coal strata here is to the north east, each seam of coal has a dip inwards from the wings or verges upon the line of bearing, so that each field taken simply in the abstract as a stratum of coal, is in its form the portion of a cup or flat bason, a form very generally found in coal fields. The Clackmannanshire coal strata keep the dip formerly mentioned, till the north field approaches the Ochill mountains, when the dip suddenly changes, and the strata rise towards the mountains, so that at their foot the various coal strata and coals are found conforming to the acclivity of the mountain face, and perfectly regular. **Coal strata.** The coal strata are cut through in many of the glens by the water, exposing to view objects highly interesting to the geologist. The junction of the coal strata with the mountain rocks is most distinctly seen at the Westertown Glen of Tillycoultry. The Ochills are the boundary line of the great coal field of Scotland upon the north, no coals having been found beyond them. The strata which compose this coal field are, varieties of sandstone, reddish, white, and grey colours, some of which are excessively hard, various kinds of shale or argillaceous shistus, bands of ironstone, and fire clay; greenstone, from its situation, may also be reckoned amongst the coal strata; as in one of the hill glens, it is either the lowest of the coal strata, or the first or uppermost of the mountain rocks, balls of ironstone are found abundant in the schist or shale. In the lowest series of the strata, and upon the verges of the coal field in the line of bearing, limestone is found, which arrangement agrees with many of the coal fields in Great Britain. Organic remains are found very abundant in the strata, particularly of the fresh water muscle in the ironstone, and of trees and plants in the sandstone, schist, and coal; many of these are of plants which are not found growing in Great Britain, but appear to belong to the equatorial regions. There has been ascertained in the Clackmannanshire coal field a great number of seams or beds of coal, varying in thickness from an inch to nine feet, amounting in the aggregate to fifty-nine feet of coal: the thinnest seam which has been wrought is twenty-seven inches thick. All the coals are of the open burning kind; and in general both cubical and slate coal are found in the same bed, which, in working, turn out in large quadrangular masses. None of the Scotch smithy coals are found here, or any in quality similar to the Northumberland caking coals. Many collieries have been opened and are now carrying on here; they are in every parish, Logie excepted, which lies west of the verge of the workable coal seams. Some of these collieries have been open for two centuries, and are wrought to a considerable extent, the deepest pit being about fifty-five fathoms. The collieries, as to the scale of working, stand thus: Alloa, Sauchy, Clackmannan, Dollar, Kennet, Tillycoultry. The present annual output of coals may be taken at 130,000 tons, the greater part of which is exported to Leith, Taywater, and Dunbar. The noxious air commonly generated in the coal mines is carbonic acid gas, termed choak damp; it issues continually from the fissures of the whole (heal) coal and from the strata adjoining. Attention requires to be paid to the ventilation of the pits, otherwise this gas would quickly accumulate, and prevent the workmen entering the mine. No vestige of (inflammable air) hydrogen gas was ever seen in the coal mines till lately, when, in driving a stone mine at Old Sauchy colliery, it accumulated and exploded without producing any bad effect. The water produced in the mines is very hard, being in general much impregnated with lime and sulphur. **Ironstone.** Ironstone is the only other mineral wrought to any extent, which is used at the Devon iron furnace, in the parish of Clackmannan; it is of the common argillaceous kind, and yields from 25 to 30 per cent. of iron. Freestone is found in abundance, but none of it is remarkably fine either in colour or quality. Large blocks of greenstone are found thinly scattered over the surface of the county; but as no rock mass of that kind is found nearer than six miles to the westward, many theories have been given by philosophers, as to the natural means by which they have been transported from their original rock. The great mass of greenstone rock in this county is Abbey Craig near Stirling; it is bold, rugged, and precipitous towards the south-west, and slopes or dips to the north-east, having no superincumbent rock strata. The bottom of the precipice is covered with huge blocks of this rock, which in former ages must have fallen down. This rock, in its general structure, is rudely columnar, above 100 feet thick, and rests upon the common alternating series of coal strata, composed of sandstone, shale, and coarse limestone, mixed with iron. In this last, petrified shells are abundant. The surface slope of this immense rock seems to conform with the dip of the strata on which it rests, a point in the mineral field, worthy of the attention of the geologist. This rock, in its fracture, is found both of an open and close grain, and of crystallised appearance, composed of feldspar and hornblende, with minute crystals of pyrites. It is difficult to break under the hammer. It is tough rather than splintery. It dresses with a regular face, similar to the Aberdeen granite; but its particles are much more cohesive than the granite: this superior quality induced an ingenious miller, of the name of Brownhill, to try this rock as a substitute for French burstones in the manufacture of flour, as the burstones, on account of the war, had become very high in price; he succeeded beyond his expectation. And so much are these millstones approved of, that they are in general request both for flour mills and distilleries for gristing. They are built in pieces, similar to the burstones; are uniform in the cutting surface, and dress well, a quality deficient in the burstones. As a proof of their utility, above 300 pairs of these millstones are now used in Scotland and England. They sell at from sixteen to twenty guineas a pair, whereas burstones cost about sixty guineas; hence an important acquisition is made, and also a great saving of expence. The Society for the encouragement of Arts, presented Brownhill with one hundred guineas for the discovery.

Manufactures. As to the manufactures carried on in the county, that which is upon the greatest scale, and in which large capitals are embarked, is the distillation of spirits, (whisky.) There are no less than six large distilleries in this small district: Kilbagie, in the parish of Clackmannan, is the most extensive. These works yield to government a revenue of about L. 723 per annum, on each gallon of the licensed still, when working from grain, and employ a great number of people; part of the spirits is sent to London, but the greater part to Leith and Glasgow. When the distillation from corn is allowed, great numbers of cattle are fed at these works from the grains and dreg, and the consequent produce of manure, has greatly contributed to the high improvement of the adjoining lands. It is estimated that every gallon of licensed still will produce grain and dreg to fatten, in the best manner, two oxen of 40 stones (Dutch) each; but when sugar is used in distillation in place of grain, no cattle are fed. These works are carried on in the most scientific, regular, and systematic manner; and, it is remarkable, that the workmen employed at them are a very sober set of people, notwithstanding the free access they have to spirits at all times.

Ales are made to a considerable extent in Alloa: they have a name in the market, and are in great request both in Scotland and England.

The making of pig-iron is carried on at the Devon iron-works, in the parish of Clackmannan, where there are two blast furnaces, impelled by a powerful steam engine. About 60 tons of pig-iron is produced here weekly; a small part of it is used by a foundry at the works, but the greater part is sold to other founders. The manufacture of coarse woollen cloth, named serges, has for a long period of years been carried on at Tillycoultry, and still continues; and there is a woollen manufactory at Alloa on a small scale; there is, besides, manufactures at Alloa for common glass bottles, bricks, tyles, ropes, sails, common pottery, and leather. There is a bleachfield of considerable extent at Dollar, chiefly employed by the Dunfermline table damask manufactories, and the distillation of the pyroligneous acid is carried on in the parish of Clackmannan: the acid is sold to the chemical works at Glasgow, and the charcoal to the founders. This is an object to which more attention might be paid in Scotland, where woods are cutting, provided there is a full demand for the acid. Ship-building is carried on at Alloa, where there is an excellent graving dock for vessels of large burden. There are many muslin weavers all over the county, but these are all employed by Glasgow houses.

Machinery. There is much machinery in the county, driven by water, steam, and horses; it is generally constructed on the most approved principles, and some of it very powerful. There is a steam engine at Sauchy, which lifts, from the depth of 280 feet, a million gallons of water every 24 hours.

Antiquities. Regarding antiquities, the towers of Clackmannan and Alloa are upwards of 500 years old, and there is an old baronial tower at Sauchy in a retired situation. The abbey tower of Cambuskenneth, in the parish of Logie, is also of considerable antiquity: In this abbey it is said that several of the kings of Scotland are buried, and in particular James III. These towers are of a rectangular form, and built with large square stones, the masonry plain and substantial, the walls of Alloa tower being eleven feet thick. Castle Campbell, in the parish of Dollar, named also Castle Gloom, is a ruin of ancient date; the time of its being built is not exactly known, but it was in possession of the Argyle family in 1465; it is most romantic, wild, and gloomy, as to situation; is built on an insulated conical hill, above which the surrounding hills rise to a great height immediately adjoining excepting on the south. There is a singular narrow cut made in the solid rock, from the south front of the castle to the bottom of the glen, named Kemp's Score; it is said to have been a stair for procuring water for the castle. John Knox, the celebrated reformer, preached in front of this castle; and here the sacrament of the supper was dispensed amongst the first times it was dispensed in Scotland. Roman and other ancient coins have been found in this county, and also a few very ancient weapons.

Roads. With respect to eminent persons, natives of this county, the names of Bruce, Erskine, and Abercromby are conspicuous: they are enrolled in the page of history, and in other parts of our work they have received the tribute which is due to their memory.

Projected improvements. The county roads are excellent, and in every direction, which have tended much to improve the country. An improved cast-iron rail-way is laid from the Alloa colliery to the harbour, where a horse brings down eight tons of coals, and returns with the empty waggons, so that one man and one horse do as much work in one day, as 27 horses and 27 men did in the same time 60 years ago. There is a good ferry at Alloa to the opposite side of the river; and three packets sail regularly betwixt Alloa and Leith. Amongst the projected improvements in this district, a survey was made by Mr Rennie, the celebrated engineer, in order to ascertain the expence of throwing a bridge across the Forth at the Alloa ferry. He pronounced the work practicable, and gave a handsome design for an iron bridge, the estimate for which was £150,000. This bridge would be of great benefit, but the expence is such as to prevent the plan from being executed at present. Another evident improvement which has been projected, is a canal from Alloa through the Carse of Stirling. This would be of the greatest benefit, as by its means lime and coal could be carried with ease into a country in great want of these articles. Grain, slates, &c. would be returned; as the ground through which the canal would pass is flat, and composed of clay, the expence would be very moderate. A project was brought forward many years ago, by the commissioners for the improvement of Scotland, to render the Devon navigable; a plan and estimate was made, but no steps were taken to carry the scheme into effect. A branch from the before-mentioned projected canal would be more suitable for trade, on account of the heavy floods which occasionally happen in the Devon.

There are several artificial collections of water in the county for the purpose of driving machinery, the largest of which is Gartmorn Dam, made about 100 years ago by John, Earl of Mar: it covers 120 Scotch acres of land; the supply of water is brought from the Black Devon by an aqueduct some miles in length; an engineer from Wales was brought by the Earl to give his advice regarding this work, and for improving the hydraulic engines, by which all collieries, not level free, were then drained.

All kinds of timber grow well in the county, and there are many trees of very large size. The plantations are increasing every year, and are very thriving.

There are no poors rates in the county, the poor being supported by collections at the church doors and voluntary contributions. A gentleman of the name of M'Nab some years ago bequeathed, by his will, a large sum for *the education of the poor of the parish of Dollar*, which sum is now accumulated to above L. 40,000: it is not easy to conceive how so large a sum is to be applied in strict conformity to the destination of it.

The exports are chiefly coals, spirits, pig-iron, bottles, bricks, tyles, and ales. The imports are chiefly grain, sugars, timber, lime-stone, malleable iron, and groceries.

The valued rent of the county, according to the cess books, is L. 26,482 : 10 : 10, Scotch money. The population in 1811 was 11,719 souls. (R. B.)

CLADIUM, a genus of plants of the class Triandria and order Monogynia. See BOTANY, p. 113.

CLAIRAUT, ALEXIS CLAUDE, a celebrated French mathematician and natural philosopher, was born at Paris on the 13th of May 1713. His father, Jean Baptiste Clairaut, who was a teacher of mathematics at Paris, and member of the Royal Academy of Sciences at Berlin, had no fewer than 21 children. Our author was the second child, and the third was carried off by a premature death at the age of 16, after he had published an able work on the quadrature of the circle, and the hyperbola.

Young Clairaut was taught the alphabet upon the figures of Euclid's Elements, and such was the rapidity of his progress, that, at the age of 4 years, he was able both to write and read. He was instructed in the principles of arithmetic by the most simple and ingenious methods; and a love of the military profession, which he early displayed, was employed by his father as a powerful stimulus to the study of mathematics, and other branches of knowledge, which were represented as necessary accomplishments in a young soldier.

At the age of nine years, his attention was directed to M. Guisnee's Treatise on the Application of Algebra to Geometry. With the help which he received from his father, he speedily read this work, and, after studying it a second and a third time by himself, he resolved the greater number of the problems in a more simple and ingenious manner than the author himself. Clairaut now began to experience the delight which springs from the successful exercise of genius, and he continued his studies with an intensity of application, which, if not seasonably checked, would have endangered his health. At the age of ten, he read the Marquis de L'Hopital's Conic Sections, but he experienced considerable difficulty in making himself master of the subject. M. de Lisle, who was visiting his father, happened to see young Clairaut with this volume in his hands, and remarked, with a kind of sarcastic severity, that he could understand this book only by its title and its cover. The young geometer was affronted with the remark, though he felt it to a certain degree true, and he gave himself no rest till he was completely master of the subject. He next studied the analysis of infinites of the same author, and initiated himself into the differential and integral calculus.

The reputation of Clairaut, which was hitherto confined to his own friends, now began to extend with rapidity. The celebrated M. Nericaut Destouches having just arrived from England with his lady, who was about to be confined, took lodgings immediately below the house of Clairaut, and sent up a request to the family to make as little noise as possible, both on account of his wife's indisposition, and as he was himself employed in writing his fine tragedy of the *Philosophe Marié*. This request was so scrupulously attended to, that M. Destouches went in person to thank M. Clairaut for his kindness. He was surprised to find, that he had been living below a family of 11 children; and he was so much pleased with the young mathematician, that he introduced him to the Abbé Bignon, and to other celebrated members of the Academy.

About this time, M. Clairaut removed to another house, in which there was a small room, which was allotted to the use of our author and his younger brother, of whom we have already spoken. This room was so situated, that they could go in and come out without being perceived, and the two brothers did not fail to abuse this advantage. They procured a flint, by means of which they might light their candle, and when the family imagined them to be buried in sleep, they were eagerly engaged in the study of geometry. Alexis was now secretly occupied with a memoir on four curves of the third order, which he had newly discovered, and by means of which he could find any number of mean proportionals between two given lines, and he wished to surprise his father with this memoir when completed. Before it was finished, however, the geometrical plot was detected, and the young culprits received a severe reprimand. Delighted with the discovery of the new curves, M. Clairaut presented his son to the Academy of Sciences, for the purpose of reading his memoir to that learned body; but his size bore so slender a proportion to the abilities which were displayed, that it was only after a rigid examination of the young man, that the academicians believed him to be the author of the discovery. Father Reyneau, whose *Analyse Demontrée* had first roused the genius of D'Alembert, and who was present at this meeting of the Academy, burst into tears of joy at the exhibition of such wonderful and premature talents. The memoir of our author was published in the *Miscellanea Berolinensia* for 1724, with an honourable certificate from the Academy.

About this time, Clairaut laid the foundation of his excellent work *Sur les courbes a double courbure*, which he finished at the age of 18, with an assiduity which threw him into a violent fever. He continued his investigations on this subject, and in 1730 they were published, with a certificate from the Academy, which expressly stated, that the author had accomplished, at the age of 16, what would have done honour to the most celebrated geometers.

The academicians were now desirous to rank Clairaut among their number; but, by the rules of the Academy, this could not be accomplished till he had reached his 20th year. Application was, however, made to the king, and a special dispensation was granted in favour of the young candidate, who, on the 14th July 1731, was admitted adjunct mechanician at the early age of 18.

The joy with which this event naturally inspired M. Clairaut and his family, was painfully alloyed by the death of the younger brother, whom we have already mentioned, and who was carried off in two days by the small-pox.

After Clairaut had recovered from this dreadful shock, which for a while threatened his own life, he chearfully accepted an offer from M. Maupertuis, to accompany him to Basle on a visit to John Bernoulli. On his return from this excursion, with which he was peculiarly delighted, he found his associates in the Academy occupied with the question of the figure of the earth, and he resolved to devote his attention to this important subject. With this view, he and M. Maupertuis retired to Mount Valerien, where they formed the project of a voyage to Lapland, in the execution of which our author was of the most essential service. The Marchioness of Chatelet having taken a fancy for the study of geometry, went frequently on horseback to visit Clairaut at Mont Valerien; and it was for this lady that he composed his *Elemens de Geometrie*, which appeared in 1741.

After his return from measuring a degree of the meridian in Lapland, the king granted him a pension of a thousand livres, which in less than a year was followed by another that had been vacated by M. Chevalier.

In the year 1758, on the death of Bouguer, his pension of 3000 livres was divided between Clairaut and Le Monnier; and in consequence of this encouragement, he laid before the Academy an excellent Memoir on Naval Tactics.

It would lead us much beyond the limits of a biographical article, were we to follow Clairaut through the numerous memoirs which he communicated to the Academy of Sciences. The progress of his researches, and the various subjects which attracted his attention, will be more readily seen from the list of his Memoirs which is given at the end of the present article. We shall therefore only notice at present such of his works as have been most conducive to the advancement of science.

In his *Theorie de la Figure de la Terre suivant les principes de l'Hydrostatique*, which appeared in 1743, he has treated this interesting subject with unusual ability. He has determined, upon the Newtonian theory, what would be the figure of the earth if it were wholly fluid; and either uniformly dense, or consisting of concentric strata of variable density: He has examined what would take place if a part of it were rendered solid; and by an application of the same principles, he has given the first philosophical theory of capillary attraction.*

---

* See CAPILLARY *Attraction*, vol. v. p. 411. where we have given an account of Clairaut's Theory.

In the year 1747, Clairaut shared the honour, along with Euler and d'Alembert, of having solved the problem of three bodies. In the three solutions of this great problem which had been separately obtained, without any communication, by these illustrious mathematicians, it turned out, to the astonishment of them all, that the calculus gave only half the observed motion of the moon's apogee. Clairaut proposed to make a slight alteration upon the law of gravity, in order to produce a correspondence between the theory and the observations; but this idea was warmly attacked by Buffon, and Clairaut at last discovered that he and his learned associates had neglected some small quantities in the series, and that the result thus corrected was perfectly consonant to the theory of gravitation. He gained the prize for this subject, which was given in 1751 by the Academy of St Petersburgh, and in 1754 he published his Lunar Tables, which were founded upon his own solution of the problem of three bodies, and which greatly exceeded in accuracy those that had been formerly in use. A new and correct edition of this work was published in 1765.

The application of the problem of three bodies to the theory of the comet of 1759, formed the most important epoch in the life of Clairaut; but as we have already discussed this subject at sufficient length both in the article Astronomy and in the life of D'Alembert, we cannot resume it in this place.

Next to the lunar theory, the most important subject which then exercised the genius of mathematicians, was the improvement of the achromatic telescope. This subject occupied much of Clairaut's attention, and he published the result of his researches in three memoirs, which appeared in 1756, 1757, and 1762, and which contain a most complete investigation of the various forms in which achromatic object glasses may be constructed. In the course of this enquiry, Clairaut discovered that the coloured spaces in equal spectra produced by substances of different dispersive powers, were not proportional, and therefore that a *complete* correction of colour could not be effected by two kinds of glass. This beautiful discovery of a secondary spectrum was made about the same time by Boscovich, without any knowledge of what Clairaut had done; and this able mathematician has shewn how a more complete correction of colour may be obtained by employing three different substances in the construction of the object-glass. This curious subject, so intimately connected with the perfection of the achromatic telescope, has been recently investigated by Dr Brewster, who has determined the relative proportions of the coloured spaces for a great variety of transparent bodies. He has found that the uncorrected colour generally increases with the difference between the dispersive powers of the two substances by which the opposite dispersions are produced; that sulphuric acid exceeds all transparent substances in its action on the green rays, while oil of cassia exerts the least action upon them of any known substance, and that there is a *tertiary spectrum* which may be formed even when the opposite dispersions are produced by two prisms or lenses of the same substances. The application of these results to the improvement of the achromatic telescope, will be pointed out in the article Optics.*

In order to render his investigations of real utility to the practical optician, Clairaut began to reduce all his results into tables, and to compute the thickness and radii of the different lenses which were requisite to form an achromatic object-glass; but he unfortunately did not live to finish this work. Although he had laid down a rule never to sup in Paris, yet he was on one particular occasion induced by some of his friends to transgress it. So fatal was this rash indulgence, that he scarcely lived to repent it. He was attacked with indigestion and rheumatism, which baffled the skill of his physicians, and carried him off on the 17th of May 1765, in the 52d year of his age.

List of Clairaut's separate works.

The following is a list of the works which he published separately.

Recherches sur les courbes á double courbure. Paris, 1730, in 4to.

Eléméns de Géometrie. Paris, 1741, in 8vo.

Eléméns d'Algèbre. Paris, 1746, in 8vo.

Théorie de la Figure de la Terre. Paris, 1743, in 8vo.

Tables de la Lune. Paris, 1745, in 8vo.

List of his Memoirs.

The Memoirs which he published in the *Memoires de l'Academie* are the following:

Observations sur un instrument par le moyén duquel on peut prendre les Angles, et faire les calculs arithmetiques, 1727. Hist. 142.

Nouvelle maniére de trouver les formules des centres de gravité, 1731, 159.

Obs. sur les courbes que l'on forme en coupant une surface courbe quelconque par un plan donné de position, 1731, p. 483.

Des épicycloïdes sphériques, 1732, p. 289.

Maniere de trouver des courbes Algébriques et rectifiables sur la surface d'un cone, 1732, p. 385.

Solution d'un problême de Géométrie, 1732, p. 435.

Obs. sur quelques questions de *maximis* et *minimis*, 1733, p. 186.

Determination Géométrique de la perpendiculaire, à la méridienne, tracée par M. Cassini, avec plusieurs méthodes d'en tirer la grandeur et la figure de la Terre, 1733, p. 406, H. 59.

Solution de plusieurs problêmes, où il s'agit de trouver des courbes dont la propriété consiste dans une certaine relation entre leurs branches, exprimée par une équation donnée, 1734, p. 196.

Remarques sur la méthode de M. Fontaine, pour résoudre le problême ou il s'agit de trouver une courbe qui touche les côtés d'un angle constant dont le sommet glisse dans une courbe donnée, 1734, p. 531.

Obs. sur le nouvelle méthode de M. Cassini pour connoître la figure de la Terre, 1735, p. 117. H. 51.

Examen des différentes oscillations qu'un corps suspendu par un fil, peut faire lorsqu'on lui donne une impulsion quelconque, 1735, p. 281, H. 92.

Examen de la résponse de M. Fontaine á mes objections, sur la méthode pour trouver une courbe qui touche continuellement les côtés d'un angle constant dont le sommet glisse dans une courbe donnée, 1735, p. 577.

Solution de quelques problêmes de dynamiques, 1736, p. 1. H. 105.

Obs. sur la mesure de la Terre par plusieurs arcs de meridien pris á différentes latitudes, 1736, p. 111.

De l'aberration apparente des etoiles causée par le mouvement progressif de la lumiére, 1737. p. 205. H. 76.

Des centres d'oscillations dans des milieux resistans, 1738, p. 159.

Suite d'un mémoire donnée en 1733 qui a pour titre: *Determination Géomètrique de la perpendiculaire á la Méridienne*, 1739, p. 83.

---

* See Brewster's *Treatise on New Philosophical Instruments, with Experiments on Light and Colour*, p. 353—400. Edin. 1813.

Obs. sur la maniere la plus simple d'examiner si les étoiles fixes ont une parallaxe, et de la determiner exactement, 1739, p. 358. H. 42.

Obs. sur les explications Cartésienne et Newtonienne de la réfraction de la lumiere, 1739, p. 259.

Recherches générales sur le calcul intégral, 1739, p. 425.

De la spirale d'*Archimède* décrite par un mouvement pareil á celui qui donne la cycloïde et de quelques autres courbes de meme genre, 1740, p. 148.

Problême physico-mathématique, 1740, p. 254.

Obs. sur l'intégration ou la construction des equations différentielles du premier ordre, 1740, p. 293.

Elémens de Géomètrie, 1741. H. 96.

Obs. sur quelques principes qui donnent la solution d'un grand nombre de problèmes de dynamique, 1742, p. 1. H. 125.

Traité complet de la figure de la Terre, 1742. H. 86.

De l'Orbite de la Lune dans le Systême de M. Newton, 1743, p. 17. H. 123.

Du Systême du Monde dans les principes de la Gravitation universelle, 1745, p. 329.

Advertissement de M. Clairaut, au sujet des Mémoires quil a donnés en 1747 et 1748, sur le systême du Monde dans les principes de l'Attraction, 1745, p. 577.

Réponse aux Reflexions de M. Buffon, sur la loi de l'Attraction, et sur le movement des Apsides, 1745, p. 529.

Réponse a la Replique de M. de Buffon, 1745, p. 578.

Réponse au nouveau Mémoire de M. de Buffon, 1745, p. 583.

Eléméns d'Algébre, 1746. H. 87.

De l'Aberration de la Lumiére des Planétes, des Cométes, et des Satellites, 1746, p. 539. H. 101.

De l'Orbite de la Lune, en ne négligeant pas les quarrés des quantités de même ordre que les forces perturbatrices, 1748, p. 421.

CLAIR OBSCURE. See PAINTING.

CLARE, a county of Ireland, in the province of Munster, bounded to the south and east by the Shannon, which divides it from the counties of Tipperary, Limerick, and Kerry; on the west by the Atlantic ocean; and on the north by the county of Galway. It extends from north to south 33 English miles, from east to west 66, and its superficial measurement is about 1195 square miles. The sea-coast by which this county is bordered, consists of a chain of basaltic rocks. Towards the centre of it is an arm of the sea, or rather of the Shannon, known by the name of the Fergus river. It is remarkably bare of wood, and abounds so much with limestone, that whole tracts are entirely beds of it, the surface even having the appearance of a mass of stone.

Soil.

The soil in this county is of various quality, some being of the nature of fattening and meadow ground, other parts consisting of light limestone pasture fit for rearing sheep and young cattle, and there is a great deal of arable land; likewise extensive bogs, and some mountain land. Mr Young states that the Corcasses, a tract of ground consisting of about 20,000 acres, which extend along the Fergus and the Shannon, are peculiarly adapted to the fattening of bullocks, and that at the time he travelled there, 4000 were annually fattened on them. At present also, the store-cattle of Clare are more numerous than in any of the adjoining counties. Mr Young describes the soil of the Corcasses as either a rich black loam, or a deep rich blue clay. The higher lands are chiefly limestone, or limestone gravel. The bogs in the county afford a valuable supply of fuel. Those particularly near the Shannon yield a handsome return to the proprietors, by furnishing this article for the Limerick market. The worst grounds in the county are the eastern mountains, the peninsula north of the Shannon, and the barony of Burren. Even this last, however, by the luxuriant pasturage interspersed among the seemingly barren hills, affords support to great numbers of cattle and sheep; and the rocks themselves are limestone. The rent of the green land, without including the Corcasses, has been averaged at a guinea and a half per acre. The latter are let so high as from 3 to 5 guineas per acre.

Agriculture.

The kind of grain chiefly cultivated in the county of Clare, and indeed in the whole of the surrounding district, is oats; and the establishment in this quarter of corn-buyers, who ship that grain for Scotland, has induced the farmers to sow with it many acres in these parts, which would otherwise have been covered only with sour grass. Indeed a large portion of the tillage of this county, especially that on the sides of mountains, or amongst rocks, is performed by the spade, the unevenness of the surface, as well as often the circumstances of the cultivator, not admitting of the use of a plough and horses. Rape is sown here in considerable quantity on the mountain or boggy grounds. Some of the seed which is the produce, is pressed into oil at mills near Killaloe, and the rape cakes are sent to England for manure. For the most part, however, the rape seed is sent thither in its original state, and it is there pressed, for the use of the woollen manufacturers in Yorkshire. Beans were formerly grown here in large quantities, but since they have ceased to be used for bread by the peasantry, the cultivation of them has been laid aside. Flax is sown, but not extensively, for home consumption. In the preparation of the ground

for some of the crops, chiefly rape and potatoes, the practice of paring and burning, though illegal, and though much discountenanced by landlords, is still retained in this county, as well as in other parts of Ireland, especially where the ground is coarse, and in a little improved state. Some attempts have also been made towards increasing the value of the bogs in the county by means of irrigation, which has the effect of converting them into good meadow land.

Cyder orchards.

The cyder orchards of Clare have been much noticed, but they seem to be at present upon the decline. With respect to the Cackagee cyder, the extraordinary flavour of which has been so highly celebrated, there is rather a want of accurate information. Some say, that the finest is made from the juice of the first squeezing, that of the second being reserved for the common cyder; while it is asserted by others, that only one side of the apple, namely that which hangs towards the sun, is employed in the preparation of the best kind of cyder; and some allege, that the apples are thrown into heaps, and are not squeezed till they have attained a certain degree of fermentation. It does not appear, that the species of fruit from which this produce is obtained, is much cultivated, nor itself consequently of much importance. The apples from which it is made are of a remarkably sour nature, and grow chiefly in the neighbourhood of the sea, and in parts where there is seldom any frost or snow. They are said to be bad bearers, to which may in part be owing the scarcity of the article.

Plantations.

Though in the county of Clare one may travel for many miles over limestone rock without seeing so much as a bush, and though there is perhaps hardly any thing in it which merits the denomination of a wood, there are yet some plantations. The extent of ground which these cover has been estimated to be to the amount of nearly 800 acres.

Cattle.

Clare produces excellent cattle of the long-horned breed. There are also large flocks maintained here of long woolled sheep. The regular dairies in the county are few. Some persons let their cows to their tenants, whose wives retail the milk with a very considerable profit. Sheep's milk is frequently mixed with cow's milk for the market; and the filthy custom still prevails of permitting the calf to suck two teats while the dairy maid empties the other two, the consequence of which is that the dribbling from the calf's mouth falls into the pail.

Manufactures.

In respect to manufactures the produce of the county of Clare seems hardly, in any instance, to go beyond its own consumption. Spinning is by no means prevalent, and the excellent Clare dowlas is scarcely any longer known. The only manufactures indeed for which there is a market within the county, are coarse flannels and worsted stockings. At the same time, it is to be observed, that the wearing apparel of the lower orders, is, for the most part, prepared in their own families. The usual clothing of the men is a kind of frieze thus made at home, and which is of a much superior quality to what is commonly to be had in the shops. Some parts of the women's dress are often of the same kind, or more frequently of a coarse flannel dyed of a bad red colour, which is also of their own preparation. Kelp is made along the shore of this as well as of the adjoining counties. Sea-weed, in general, has been long known as a valuable manure. Sea sand also, with which this coast abounds, is used here for the same purpose, to a great extent, and with proportionate advantage.

Harbours.

The west coast of Ireland, in general, is subject to extremely violent storms. It is said that near Doolen, in this county, blocks of limestone, 10 or 12 feet in diameter, are thrown up sometimes on ledges of rocks, which are several feet in height. At the same place there is a barrier of water-worn stones, some of them many tons in weight, raised above 20 feet high across a small bay where fishermen used to land from their boats, and where their former quay, surrounded with huts, remains many yards from the sea. Against the fury of the winds prevalent in this quarter, though there is no want of harbours on the coast, yet along the whole extent of this county there is not one in which ships may lie with safety. Its ports on the Shannon are by no means considerable.

Rivers.

The only rivers in the county of Clare that are deserving of notice, are the Shannon and the Fergus. The former of these, as it approaches the confines of this county, is expanded into Lough Deingheart. It contracts its limits again from the vicinity of Killaloe, but between Clare and Kerry, the breadth of this noble river varies from one to five miles. The Fergus, which is the principal river that has its source within the county itself, admits not of the navigation of any vessels of greater burden than sloops. Its estuary, however, at its junction with the Shannon, is very wide and full of islands. This river, and indeed several others in Clare, dip under ground in some part of their course.

Lakes.

There are in this county also many turlachs, or spots, which at one time are lakes, and at another sound sheep walks. The most remarkable of these is that at Kilcorney, in Burren, where the waters issuing often more than once a year from a spacious cave, deluge the whole adjacent flat grounds. There are some lakes in the county, but none of much consideration.

Plants.

The plants and minerals with which the mountainous and stony parts of the county of Clare abound, are many of them deserving of attention. There are found here several of those which are considered to be the rarer plants of Ireland. Such are the *Iris fœtidissima*, the *Arbutus uva ursi*, the *Rubus saxatilis*, the *Cardamine bellidifolia*, the *Asperula cynanchica*, the *Lysimachia vulgaris*, the *Butomus umbellatus*, the *Sedum telephium*, the *Potentilla fruticosa*, the *Dryas octopetala*, the *Mentha pulegium*, the *Turritis hirsuta*, the *Cheiranthus sinuatus*, the *Gnaphalium dioicum*, and the *Satyrium hircinum*.

Minerals.

The mineralogy of the county has been but little explored. Lead ore is said to occur in various places; in some of which it was formerly raised and smelted. Manganese is abundant, and there are different ores of iron, particularly micaceous iron ore, and red iron stone. Boate mentions iron works in Clare, which belonged to English merchants, in the early part of the 17th century. At Doolin in Burren, there has been found a vein of purple fluor spar, similar to that brought in ornaments from Derbyshire, some of the specimens having cubic crystals; but the extent of the vein is not known, and no attempt has been made to apply it to any useful purpose.

Political division.

Clare county is divided into 9 baronies, and 79 parishes, most of which are comprehended within the united sees of Killaloe and Kilfenora. These 79 parishes, in consequence of unions, form only 30 benefices, which too have not all churches. The proportion of the Catholics to the Protestants in this county, has not been very precisely ascertained. The gentry are, for the most part, members of the established church. But the graziers, who possess very considerable property, both in leases and stock, are said to be all of the Catholic religion. Indeed, it has been alleged, that the tenants are universally Catholics; those who pretend to be Protestants being, in fact, so only in appearance, and from interested motives. The Catholics in this county are certainly very numerous. Two gentlemen of this persuasion are called on the grand jury. The county militia consists almost entirely of Catholics, with the exception of the officers.

Population. The number of inhabited houses in the county of Clare, was, in the official return of 1791, stated to be 17,396, from which the amount of the population may be concluded to be about 104,000. Two members represent this county in the House of Commons. There is one also for the burgh of Ennis. This, which is the county town, is situated on the Fergus, and is the only town of note in the shire.

History. The ancient name of the county of Clare was Thomond. It was a principality under the O'Briens, descendants of Brien Borombe, the King of Ireland, who was slain fighting against the Danes A.D. 1014. One of the family was acknowledged King of Thomond by Henry III.; and Murrough O'Brien, on resigning the old title of prince, was made Earl of Thomond by Henry VIII. Thomas de Clare, son of the Earl of Gloucester, having come to Ireland in 1276, and settled in this county, had a large portion of it conferred on him in property by its petty prince, or, according to other accounts, by King Edward I. From him, or some of his family, the county received its present name. It had always been considered as a part of Munster, as is implied in its original appellation; but when Connaught was divided into counties in 1562, Clare was included in their number. As at that time, however, each province had a peculiar governor, called lord president, and as the earls of Thomond having possessions in other parts of Munster, were mostly connected with it, they obtained, upon their petition, to have the county of Clare again comprehended under that province in 1602. In this connection it has since continued, and its bishopric is subordinate to the primacy of Munster.

In the county of Clare, there are several interesting remains of antiquity; such as the Ogham inscription on Callan Mount; also various ruins, particularly those of Quin Abbey, and the island of Inis Scattery. See Beaufort; Young; and Wakefield's *Statistical and Political Account of Ireland, &c.* (K)

CLARET. See WINE.

CLARINET, in music, is a wind instrument, very common in military bands, having, however, rather a coarse croaking kind of tone, except in the hands of the most expert performers, some of whom have places in the best concerts.

C and F are the only keys that are usually in good tune on the common clarinets, the scale of which reaches from E below the bass cliff, to *e*, an octave above the treble stave. For general use in the orchestra, the performers have also B♭ clarinets, A clarinets, D clarinets, B clarinets, and G clarinets, for accompanying pieces in these keys. John Christopher Denner, of Leipsic, is said to have invented this instrument, sometime about the year 1600. (ϱ)

CLARION-STOP, in music, is the name of a range of reed pipes on the organ, sometimes called the octave trumpet-stop, from its near resemblance to the upper notes of that instrument. The notes of this stop are tuned an octave higher than those in the open diapason, and an octave higher than the trumpet-stop. The clarion-stop is never used alone, but in conjunction with other stops, to give power and effect to the chorus parts. (ϱ)

CLARISIA, a genus of plants of the class Diœcia, and order Diandria. See BOTANY, p. 340.

CLARKE, SAMUEL, an eminent divine and philologist, was born at Norwich in the month of October 1675. His father, Mr Edward Clarke, a gentleman of high respectability, was an alderman of that city, and for some years one of its representatives in parliament. After acquiring in the grammar school of Norwich a considerable acquaintance with the learned languages, young Clarke was, at the age of sixteen, entered a student at Caius College in Cambridge. Here the splendour of his talents, and his unwearied assiduity in the pursuit of knowledge, soon attracted general admiration. The ingenious but fanciful theories of Descartes were still held in high esteem, and taught with enthusiastic zeal in the university of Cambridge. But their fallacy was easily detected by the penetrating genius of Clarke, who, young as he was, had carefully studied and thoroughly understood the *Principia* of Newton, then recently published; and while the sublime discoveries of that great philosopher were slowly making their way against ancient prejudices, and were comprehended and appreciated only by a few profound mathematicians, this youthful admirer was meditating the most effectual plan of recommending them to more general observation. With this view he undertook the arduous task of translating from barbarous into elegant Latin, Rohault's *System of Philosophy*, then the text book in the university, to which he subjoined a variety of judicious and excellent notes, calculated to lead the student insensibly to the perception of the absurdities of the Cartesian hypothesis, and to the adoption of the new theory. This task he executed with great ability, and complete success. His translation of Rohault, passing through four editions, continued for many years the standing text-book in the university, till it at length gave way to the avowedly Newtonian publications of Rutherforth and Rowning.

Having directed his views to the church, he now gave his whole attention to the studies which he considered necessary to qualify him for the able and faithful exercise of the sacred office. He began by perusing, in the original languages, the scriptures of the Old and New Testament, and the writings of the primitive Christian fathers; his accurate knowledge of which is admirably displayed in many of his theological publications. Soon after taking holy orders, he was introduced by Mr Whiston to Dr Moore, bishop of Norwich, an ardent admirer of literature, and a zealous patron of learned men. On the collation of Whiston to the living of Lowestoffe, (1698), the bishop appointed Mr Clarke his domestic chaplain. During the twelve years that he remained in this situation, he lived with his learned patron on the friendly and familiar habits of a brother; and the bishop, at his death, gave the most unequivocal proof of the high value which he entertained for him, by confiding to him the entire management of his family concerns.

In 1699, he published *Three practical Essays upon Baptism, Confirmation, and Repentance*, and anonymous reflections on part of a book called Amyntor, the production of Toland, who rejected as spurious the writings ascribed to some of the apostles and primitive Christians, and refused to acknowledge the inspiration of the evangelists St Mark and St Luke. These publications, though inferior in literary merit to the subsequent productions of our author, are highly creditable to his piety, and show him to have been, even at his outset in his theological career, intimately acquainted with the practices and the writings of the early Christians. His next publication was a "Paraphrase on the Gospel of St Matthew," which appeared in 1701, and was soon followed by Paraphrases on the other three Gospels of Mark, Luke, and John. His object, as he himself informs us, was to "express the full sense of the evangelists in the plainest words, and to continue the sense without interruption, by the clearest transitions he could." The admirable manner in which he has executed this undertaking, leaves us much reason to regret, that other avocations prevented him from pursuing his original intention of giving a similar paraphrase of all the books of the New Testament.

About this time, he was presented with the rectory of Drayton near Norwich, by his friend Dr Moore, who likewise procured for him a parish in that city. While he continued in that situation, he preached without notes, a practice in which he is said to have been peculiarly happy. But his powerful talents were soon to be exerted on a more conspicuous theatre. He was appointed in 1704 to preach at the lecture founded by Mr Boyle, and chose for his subject *the being and attributes of God*; his discourses on which interesting and difficult subject gave so much satisfaction, that he was reappointed to the same office the following year, when he delivered a series of sermons on the *Evidences of Natural and Revealed Religion*. In his discourses on the divine nature and attributes, he adopted the *a priori* mode of reasoning, which, though less intelligible to common minds, and therefore less generally useful than the opposite mode, is, when conducted with the abilities of a Clarke, by far the most satisfactory, and may be regarded as the highest effort of the human understanding. It was preferred by Mr Clarke, not from any conviction of its superior utility, or any ambitious desire to display his metaphysical powers; but as Hobbes, Spinoza, and other infidel writers, had employed metaphysical subtleties against religion, he thought it proper to shew that the same mode of reasoning might be employed, with greater effect, in its service. The uncommon ability with which he executed this undertaking, entitles him to rank in the highest class of metaphysicians; and he has merited the gratitude of all the friends of religion, by placing this particular proof of the existence of God in the clearest light of which it will, perhaps, admit. In his discourses on the evidences of religion, he traced the foundation of morality to the mutual relation of things and agents, to the unalterable fitness or unfitness of actions, and to the will of the Creator, evident from his making men capable of perceiving these relations and that fitness, of judging concerning them, and acting according to his judgment. He next proceeds to demonstrate, that the Christian religion is worthy of God, from the perfect conformity of its main design to the light of nature, and to all the moral obligations of eternal reason; and then proves, from the external evidence of prophecy and miracles, that this religion was actually revealed from heaven. This work, though it excited a host of opponents, is of inestimable value, as it contains the most irrefragable proofs of the divine origin, authority, and obligation of the Christian system.

The ardent wishes of his patron for his removal to London, as a scene both of honour and of usefulness more adequate to his splendid talents, were at length gratified in 1706, when his interest procured for Mr Clarke the rectory of St Bennet, Paul's Wharf. In the same year he published his letter to Mr Dodwell, who, in his *Epistolary Discourses*, had advanced the very strange positions, that the soul is a principle naturally mortal, but immortalized actually by the pleasure of God to punishment or reward, by its union with the divine baptismal spirit; and that none, since the apostles, have the power of conferring this immortalizing spirit, excepting only the bishops. This letter, says Bishop Hoadly, gave universal satisfaction; yet it engaged Mr Clarke in a new controversy, particularly with Collins, who, in his *Enquiry into Human Liberty*, produced every thing that could be plausibly said against the immateriality of the soul. This controversy, however, did not prevent the indefatigable mind of Clarke from publishing, in the same year, a translation of Sir Isaac Newton's *Optics* into elegant Latin, a task which he had undertaken at the author's solicitation; who, in return for this favour, complimented him with the sum of £100 for each of his five children.

Being now introduced at court by his friend the Bishop of Norwich, he was appointed by Queen Anne to be one of her chaplains in ordinary; and was soon after presented, at the bishop's request, to the rectory of St James's. Thus exalted to a situation in which he would have to associate with the highest characters in the state, it was thought desirable that he should take the degree of Doctor in Divinity. He repaired for this purpose to Cambridge, where he delivered a thesis on the proposition *Nullum Fidei Christianæ Dogma in S. Scripturis traditum, est rectæ rationi dissentaneum*;—"No article of the Christian Faith, delivered in the Sacred Scriptures, is contrary to right reason." On this occasion, he excited, in all who heard him, feelings of delight and astonishment, which were not soon forgotten, not only by the profound erudition which his thesis displayed, but by the powerful eloquence and classical purity of language, with which he defended it against his able and acute opponent, Dr James, then Regius professor of divinity. A few years after (1712), he gave the world a specimen of his classical taste and erudition, in his splendid folio edition of Cæsar's *Commentaries*, enriched with many judicious notes and corrections, and embellished with some beautiful engravings. Mr Addison, in a just eulogium on this work in the 367th number of the Spectator, considers it as an honour to the English press; necessarily very correct, after passing "through the hands of the most accurate, learned, and judicious writer" of the age; and affording, in the beauty of the paper and the character of the plates, "a true instance of English genius, which, though it does not come the first into any art, generally carries it to greater height than any other country in the world." About the same time, Dr Clarke involved himself in a tedious and unpleasant controversy, by his publication of the *Scripture Doctrine of the Trinity*. Before the appearance of this treatise, her Majesty's ministers, afraid of the agitation which it might produce in the public mind, then but too unsettled, sent a message to request that he would either relinquish his design, or at least delay the publication. But without regarding their application, he proceeded with his work, and submitted his opinion to the examination of the public. Whatever may be thought of his opinions on this important but mysterious subject, he at least deserves credit for the candid and judicious manner in which he conducted his investigation. Aware that it was a doctrine of mere revelation, he did not set himself to invent any ingenious hypothesis, or by metaphysical and abstract reasoning, to support any opinions concerning it already entertained. He had recourse to the scriptures themselves: he explored every text in which mention was made of the three persons, or of any one of them; and accurately examining the words employed, by the best rules of grammar and criticism, he endeavoured to fix plainly what was, and what was not, declared in scripture, respecting Father, Son, and Holy Ghost. His work provoked a number of antagonists, the most able of whom was Dr Waterland, with whom, indeed, our author was at length engaged for some time in single combat. Superior to all his opponents in wielding the weapons of controversy, they resolved to overpower him by a more formidable mode of attack. The Lower House of Convocation made a formal complaint to the bishops, in 1714, of the heterodox opinions and dangerous tendency of his obnoxious work. The bishops, though they applauded the zeal of the inferior house, and requested them to give in extracts from the book in support of their charges, evinced a very becoming spirit of conciliation and peace; and when Dr Clarke, at the instigation of some of his friends, gave in a statement of his opinions respecting the Trinity, they expressed themselves satisfied, and dismissed the complaint. It has been alleged, that in this statement Dr Clarke made a sacrifice of his private opinions to the peace and unity of the church; a sacrifice for which he has been censured or applauded according to the different views and tempers of his biographers. He himself is said to have afterwards regretted his statement, and to have been sensible, when too late, of the error into which he had fallen. It is certain, that to the last he entertained the same sentiments respecting the Trinity which he had avowed in his Scripture Doctrine.

He next engaged in a more amicable and pleasant controversy with the celebrated Leibnitz, on the abstruse metaphysical doctrines of philosophical liberty and necessity. These were points which he had deeply studied, and in the discussion of which he always excelled; but his excellence never shone more conspicuous than on this occasion, when he was pressed by the strength of so powerful an adversary. His papers on these subjects were inscribed to the Princess of Wales, afterwards Queen Caroline, through whose hands they had all passed, and who was the witness and judge of every step of the controversy. He again exposed himself (in 1718) to theological animadversion, and became involved in an unpleasant controversy respecting apostolical and primitive doxologies, by introducing some alterations into the doxologies of the singing psalms, which had been reprinted that year for the use of his church. The alterations consisted in ascribing glory to God *through* Christ, instead of ascribing equal honours to each of the three persons in the Trinity. The bishop of London published, on this occasion, a pastoral letter to the clergy of his diocese, to warn them against innovations, and to forbid them to use the new doxologies. Whiston espoused the cause of his friend Dr Clarke, whose conduct in this affair he accounts one of the most Christian attempts towards somewhat of reformation, on the primitive foot, that he ever ventured upon. He adds, however, that the bishop of London, in the way of *modern authority*, was quite too hard for Dr Clarke, in the way of primitive Christianity. About this time he was presented, by Mr Lechmere, chancellor of the Duchy of Lancaster, to the mastership of Wigstan hospital—a favour which was much enhanced by the handsome manner in which it was conferred. In 1724 he published seventeen sermons on different occasions, eleven of which had never been printed. On the death of Sir Isaac Newton (1727), he was offered the mastership of *the mint*; but as that was a preferment entirely secular, he, with a becoming respect for the dignity of his clerical character, thought proper to decline it. He shewed his gratitude and affection for his deceased friend, by publishing, in the *Philosophical Transactions* (No. 401,) an able vindication of the Newtonian theory on the velocity and force of bodies in motion, in a letter addressed to Mr Benjamin Hoadly. The last great work which he lived to publish was his celebrated edition of the twelve first books of the Iliad of Homer, which made its appearance in the beginning of the year 1729. The value of this work, which comprehended an elegant Latin translation, with a number of admirable notes and illustrations, has been fully recognised and appreciated by the learned in every country, and one whom Clarke himself had characterised, as *Criticos unus omnes longe longeque antecellens*, honoured it with the concise but high encomium, that it was *supra omnem invidiam*. The twelve last books were published in 1732 by his son, who assures us that Dr Clarke had himself finished his annotations on the three first of them, and part of the fourth.

While thus actively and usefully employed, in the full maturity of his intellectual powers, he was seized by a pleuritic affection on the 11th of May 1729, after he had gone to preach before the judges at Sergeants Inn. On the afternoon of that day, the pain abated: His physicians pronounced him out of danger, and his friends were congratulating themselves on the removal of their alarm, when, to their inexpressible surprise and sorrow, the pain shifted from his side to his head, on the Saturday following, (the 17th May,) and terminated that very evening his valuable life. After his death, an "Exposition of the Church Catechism," comprising the substance of a course of lectures which he had delivered in the church of St James's, and which he had carefully revised for the press, was published under the inspection of his brother, who likewise gave to the world a collection of his sermons in ten volumes.

In the bright constellation of genius which adorned what has been called the Augustan age of Britain, no single star, if we except the incomparable Newton, shone with more distinguished lustre than the subject of this memoir. Favoured by nature with uncommon powers of mind, he improved them by almost constant exercise, and enriched them with every thing valuable in literature and science. The knowledge to which ordinary men attain by slow and toilsome steps, he gained as if by intuition; and became eminent in all those great departments of learning, to excel in one of which is accounted no mean praise. As a profound and acute metaphysician, he has rarely been equalled; as a philologist, he has not been excelled; and he who, at the age of 17, could clearly comprehend and duly value the new revelation of the Newtonian philosophy, while yet struggling through the mists of prejudice, must be allowed to have possessed a kindred genius with its immortal discoverer. His chief attention, however, was directed to theology; the sublime doctrines of which became the favourite themes of his penetrating and comprehensive mind, and to the study of which he brought all the aids which human learning can impart. Few men, accordingly, have done more essential service to religion. With regard to his opinions on some difficult points, there will of course be a diversity of sentiment; but no Christian can withhold from him the tribute of admiration and of gratitude for his powerful defence of natural and revealed religion against their most formidable adversaries, and his singular ability and success in forcing these enemies from the strong holds in which they confided most, and in employing their artillery to their own discomfiture. It has been well observed by one of his biographers, that, "from his first

Discourse on the Being of God, to his Letter to Leibnitz on Liberty and Necessity, his writings remain, and will for ever remain, before the world, a lasting monument of a genius which could throw in light where darkness used to reign, and force good sense and plain words into what was almost the privileged place of obscurity and unintelligible sounds." His sermons are addressed, not to the passions, but to the understanding; and on every subject which he treats, his sentiments are so important and judicious, his expressions so nervous and clear, and his mode of explaining the Scripture phraseology so peculiarly happy, as to carry irresistible conviction. His character was as amiable and respectable as his talents were superior and commanding. "His piety was manly and unaffected; his charity and benevolence extensive as the whole rational creation; and the ruling principle of his heart and practice a love of the religious and civil liberties of mankind." In contemplating the life of such a man, we feel a kind of pride in reflecting what the human mind can do, what human nature can be. How few, alas! can enjoy this elevating reflection without a secret pang of self-condemnation for the neglect of their own powers, and the imperfection of their character! See *Biographia Britannica;* Hoadly's *Account of the Life, Writings, and Character of Dr Clarke,* prefixed to his works; Whiston's *Historical Memoirs of the Life of Dr S. Clarke.* (*k*)

CLAVARIA. See CRYPTOGAMIA.

CLAUDIAN, CLAUDIUS CLAUDIANUS, a Latin poet of considerable eminence, flourished in the fourth century, under the reigns of the Emperor Theodosius, and his sons Arcadius and Honorius. The place of his birth is not fully ascertained. He has been represented by various authors, as a native of Florence, of Gaul, of Spain; but the most probable accounts, concurring apparently with his own testimony, assign to Alexandria, in Egypt, the disputed honour of his nativity. He was patronized by the celebrated general Stilicho, through whose influence he rose to considerable dignity and importance. He was made a tribune and notary; and so highly did he stand in the public esteem, that the senate ordered a statue to be erected in honour of him in the forum of Trajan, with an inscription expressive of their respect for his accomplishments and worth. After the disgrace and execution of his patron, he hastily quitted court, and little is known of his subsequent history. Some spurious pieces, inserted among his poems, have given rise to an opinion that he was converted to Christianity; but his own works sufficiently confirm the assertion of Orosius, that he continued an obstinate Pagan to the last. Lardner, however, quotes him as bearing a remarkable testimony to the victory of the Christian emperor Theodosius in Gaul; a victory which was decided in his favour by a storm, so extraordinary in its effects upon the army of his adversaries, as to have been regarded by the poet himself as a visible mark of divine interposition.

Claudian, with all his inequalities, is entitled to a distinguished place among the Latin poets. The classical purity and elegance of his style remind us of the compositions of the Augustan age; and no poet has approached nearer to Virgil, in the dignity and harmony of his versification. His beauties, however, are at least equalled by his faults. His flights, though occasionally bold and lofty, are seldom sustained; and the reader, after his imagination has been fired by the glowing animation of the poet's language, is often cooled, all at once, by his dulness and insipidity. Of his numerous writings, the principal are his satire against Ruffinus and Eutropius, the rivals of his patron Stilicho; his poems in honour of Honorius and Stilicho; his Rape of Proserpine; the commencement of an Epic Poem, which he never concluded; his Idyllia and Epigrams. The best editions of his works, are those of Barthius and Heinsius; Gesner, 1759; and Burman, 1760. For further information concerning Claudian, the reader may consult Suidas, Fabricius, and Tillemont. (*k*)

CLAUDIUS, TIBERIUS CLAUDIUS DRUSUS CÆSAR, the fifth of the Roman emperors, was born at Lyons, about ten years before the birth of Christ. His father, Nero Claudius Drusus, was the second son of Livia, the wife of Augustus; and Antonia, his mother, was the daughter of Antony and Octavia. He was the nephew of Tiberius the brother of Germanicus, and the uncle of Caligula, his predecessor on the imperial throne.

From his earliest years he was subject to a variety of disorders, by which his mental powers were so much impaired, that he became the object of general contempt and ridicule. Deemed incapable of taking any active part in the government of the empire, he was allowed to remain in the condition of a private citizen, till his nephew Caligula was invested with the imperial purple. He was then dignified with the rank of senator, he was made the colleague of the emperor in his first consulship, and presiding occasionally instead of Caligula at the public games, was sometimes greeted by the acclamations of the assembly as the brother of their favourite Germanicus. Even then, however, he was held in general contempt; and in the gross indignities with which he was treated, his life was frequently exposed to imminent danger. From this state of mortifying humiliation, an event, apparently casual, raised him at length to the imperial throne. At the time of Caligula's assassination, Claudius, who was then in the palace, had retired in terror to an adjoining balcony, and concealed himself behind the hangings of a doorway. A soldier named Gratus, while roaming for spoil, observed his feet, and dragged him from his lurking place; but on recognizing his person, he fell on his knees, solicited his pardon, and hailed him as emperor. Affection for the memory of Germanicus soon induced other soldiers to join with Gratus in this expression of regard to his brother; and the new emperor, not yet recovered from his consternation, was conveyed to the camp, and lodged for the night within the ramparts. On the following morning, the soldiers formally proclaimed him emperor, and swore allegiance to him as their lawful sovereign.

The senate, after a few irregular and ineffectual attempts to restore the ancient constitution of the commonwealth, were compelled to submit to the person whom the army had chosen to invest with imperial authority; and had Claudius fallen into proper management, or been left to the free exercise of his own inclinations, they would probably have had no reason to regret their acquiescence. Clemency and moderation marked the first acts of his reign. He published a proclamation of pardon to all who had in any manner opposed his elevation to the throne, or who had been concerned in the late conspiracy against Caligula, with the exception of those only who had been actually engaged in his assassination. He annulled, as too severe and tyrannical, the laws which were then in force against treason; he abolished several oppressive imposts, which his predecessors Tiberius and Caligula had laid upon the people; and the property which they had unlawfully taken from their subjects, he restored to the injured persons themselves if alive, or else to their descendants. These gracious actions were much enhanced by the singular modesty and propriety with which they were performed. The applauses of the people seemed not to elate him, nor would he accept of the honours which the senate had decreed to him as a testimony of their gratitude and attachment. The hopes which these popular proceedings excited, were speedily reversed. Claudius was too feeble and undecided, to sustain long the virtuous and popular conduct with which his reign had commenced. He became a mere tool in the hands of his empress, the infamous Messalina, and of his ambitious and daring freedmen and favourites Pallas, Calistus, and Narcissus. By these artful and wicked confederates, he was kept in constant dread of conspiracies; all the most respectable of his nobles were rendered the objects of his suspicion; and, though naturally inclined to mercy, he became, under their baneful influence, a cruel and oppressive tyrant. Claudius, indeed, was only nominal emperor, while the imperial power was exercised, in all its terrors, by the sanguinary Messalina, and her base associates. Many ladies of the first distinction, among whom was Julia, the niece of the emperor, were put to death at their instigation; and upwards of three hundred Roman knights and senators fell victims to their suspicion and their vengeance. These enormities were often committed even without the knowledge of Claudius, who was equally blind to the licentious conduct of his infamous consort. Her ungovernable passions, however, impelled her at length to her own destruction. She became enamoured of Caius Silius, a young Roman of noble birth, and distinguished beauty; and, with unexampled audacity and infatuation in wickedness, resolved to make him her husband. By holding out to him the most flattering prospects of aggrandisement, and even the hope of elevation to the imperial throne, she induced him to divorce his wife, and to devote himself entirely to her detestable lust.

In relating the celebration of their marriage, which took place during the absence of the emperor at Ostia, Tacitus expresses a kind of fear lest posterity should refuse to credit such an enormity, and therefore takes care to inform us, that he had ascertained the truth from the testimony of some old men, who had been witnesses of these infamous transactions. The simple Claudius was the last to discover his wife's baseness, and his own dishonour; and so much was he the dupe of her artifices, that he seemed willing, even after her marriage with Silius was revealed to him, to receive her again into favour, had not Narcissus, afraid lest his own power should be annihilated by this new union, extorted from him an involuntary consent to her death. After the death of Messalina, the emperor married his own niece Agrippina, who artfully availed herself of the opportunities which her near relationship afforded her, to ingratiate herself into his favour. The abject senate had previously passed a decree to recommend and justify this incestuous union, alike revolting to human nature, and abhorrent from the Roman customs and laws. Agrippina, to secure the popular favour, reversed, as the first act of her power, the sentence of banishment which Messalina had issued against Seneca, and appointed him tutor to her son Domitius. The measures of government, however, soon convinced the Roman people, that they had only exchanged one female tyrant for another. Claudius became as completely the dupe of Agrippina as he had been formerly of Messalina. To secure the sovereignty for her own son Domitius, to the prejudice of Britannicus, the son and legitimate heir of Claudius, was the grand object to which all the efforts of her craft and her influence were directed. Nor was she more scrupulous than her predecessor in the means which she employed to promote her designs. Every person whom she could consider as an obstacle in her way, was speedily removed; and those only were admitted to offices of trust and honour, who were dependent on her favour, and devoted to her will. Her schemes were prosecuted with so little reserve, that they were easily seen through by all, and the emperor was privately apprised of the danger which threatened him. In his first alarm, he uttered some menacing expressions, which came to the ears of Agrippina. She was aware of her precarious situation, and resolved, by strong and speedy measures, to secure the grand object of her ambition beyond the chance of opposition. She therefore took an early opportunity of administering poison to her husband, in a dish of mushrooms, of which he was particularly fond. The poison was effectual, and terminated the life of this contemptible emperor, A.D. 54, in the 64th year of his age, and the 14th of his reign.

The reign of Claudius, though signalized by no warlike achievements of the emperor in person, added somewhat to the extent of the Roman dominion, and the glory of the Roman name. Corbulo and Galba sustained in Germany the reputation of the imperial army, and Plautius advanced the eagle in triumph through some of the finest provinces of Britain. With the view of sharing the honour of his generals' successes, Claudius himself came over into our island, and after witnessing some of the victories of his troops, returned to his capital to adorn his brow with the laurels which the valour of his commanders and their soldiers had earned. Nor was he less ambitious of literary renown, to which his claims were, if not juster, at least less absurd. He composed several works in the Greek and Latin languages; and we are informed by Tacitus, a very competent judge, that his meditated harangues were by no means deficient in elegance. Emulous of the fame of Cadmus and Palamedes, he endeavoured to improve the Roman alphabet by the addition of three letters. Posterity, not aware of the utility of this accession, refused to give it the sanction of custom; though, in the time of Tacitus, the new letters were still to be seen in many of the public edicts which had been issued during the reign of Claudius. He conferred a more essential benefit on his subjects and their posterity, by forming a port at Ostia, at the mouth of the Tiber, for the purpose of providing the city with foreign grain in years of scarcity; by the grand canal, which he cut, with the view of reclaiming, for agriculture, the land inundated by the Fucine lake; and especially by the completion of the stupendous aqueduct, begun by Caius, by means of which the city was supplied with the delightful waters which issued from the neighbouring hills.

On the whole, we cannot contemplate the character of this weak and despicable prince, without joining in the reflection of the judicious historian above-mentioned, that the exaltation of such a man to the imperial throne is to be regarded as an instance of that apparently capricious contingency in human affairs, which frequently mocks all human calculations.—*Mihi quanto plura recentium seu veterum revolvo, tanto magis ludibria rerum mortalium cunctis in negotiis observantur: quippe fama, spe, veneratione potius omnes destinabantur imperio, quam quem futurum principem fortuna in occulto tenebat.* Tacitus, Suetonius, Tillemont, &c. CLEOPATRA, a name given to the princesses of the family of the Lagides, as Ptolemy was to the reigning princes. *Anc. Univ. Hist.* ix. 434.

Cleopatra, the daughter of Auletes, was equally celebrated for her beauty, her accomplishments, her profligacy, and her misfortunes. She was the eldest of four children, two of whom were sons, and two daughters, and was left joint heir of the kingdom along with her brother, with whom she was to be joined in marriage, by the direction of her father's will, according to the custom of her family. As young Ptolemy was a minor at the time of his father's death, Pothinus an eunuch, and Achillas commander of the forces, were entrusted with the care of his person and education. These two favourites finding Cleopatra to stand in the way of their views, deprived her most unjustly of that share in the government which she inherited by her father's will, and drove her from the kingdom. Cleopatra retired into Syria, and having raised a considerable army, appeared at the head of it to assert her right to the sovereignty. On the other hand, the young king, with his advisers, took the field, and marched against his sister. The two armies were encamped between Pelusium and Mount Casius, when Pompey, after the fatal battle of Pharsalia, sought an asylum in Egypt, and determined to entrust himself to the prince's party. The fate of this illustrious but unfortunate Roman, and the perfidy of the Egyptians, are well known. In the meantime Cæsar, ignorant of the fate of his adversary, pursued him with all expedition, and arrived at Alexandria just as the news of Pompey's death had reached the city. The people of Alexandria were thrown into a great ferment by the intelligence, and Cæsar had very near paid dearly for his temerity, in venturing himself among them with an inadequate force. As he was prevented from leaving Alexandria, by the Etesian winds which blew during the dog-days, he ordered his forces in Asia Minor to join him. Having gained, however, the affections of the Egyptians by his affable behaviour, he soon found himself free from danger, and attempted to adjust the quarrel between Cleopatra and her brother. His interference was acquiesced in, as Auletes had left the Roman people executors of his will, and Cæsar was at that time invested with the supreme power of dictator. Accordingly advocates were appointed by each party to plead their cause before his tribunal.

Cleopatra, however, knowing that, in affairs of state, policy generally overrules the claims of right, did not wish to commit her cause to Cæsar, though it was acknowledged to be good, till he should be prepossessed in her favour. In full confidence of her charms, therefore, she sought the opportunity of a private interview. It was not easy, however, to obtain this, as the city was chiefly in the possession of the opposite party. She therefore adopted a plan, which she knew would recommend her to Cæsar as a man of gallantry. Taking along with her only one confidential servant, she went on board a small vessel, and arrived under the walls of Alexandria in the dusk of the evening. Here causing herself to be wrapped up in a mattress, she was carried by her servant, as a bale of goods, through the streets of Alexandria into Cæsar's apartment. She was laid down at the dictator's feet, and being unrolled, up started the queen of Egypt in all her charms. Cæsar was delighted with the stratagem; and, as delicacy formed no part in the character of either, they remained together all that night. Next morning Cæsar sent for Ptolemy, and desired him to receive his sister on her own terms. This was by no means acceptable to the prince: and when he was informed that his sister was then, and had been all night, with Cæsar, he left the palace in a violent rage, and running into the streets, he tore the diadem from his head, and cast it on the ground.

The whole city was immediately in an uproar, and the young prince led on the populace to storm the quarters of Cæsar, who narrowly escaped being torn in pieces. Ptolemy, however, was seized by some of Cæsar's soldiers, and the tumult was appeased for a while. Next day Cæsar proposed an accommodation, which promised fair to end the dispute. It was, that Ptolemy and Cleopatra should reign jointly in Egypt, and that Ptolemy the younger son, and Arsinoe the younger daughter, should reign in Cyprus. This proposal was agreeable to all except the party who had expelled Cleopatra, and who foresaw their own destruction in her restoration to power. New tumults were therefore excited, and a bloody war ensued, the particulars of which we shall not detail in this place, as we are only concerned at present with the biography of Cleopatra. The war was terminated by the death of Ptolemy who was drowned in the Nile, Cæsar himself, on one occasion, having nearly shared the same fate.

Cæsar having remained much longer at Alexandria than the situation of his affairs could justify, being fascinated by the charms of Cleopatra, was at last obliged to leave her, by the dangers which were gathering round him. Before his departure, he bestowed the crown of Egypt on Cleopatra, obliging her to marry Ptolemy her younger brother, with a view to gratify the people. This was throwing all the power into her own hands, as Ptolemy was then only eleven years of age. She allowed him to live, so long as he could give her no annoyance; but when he arrived at the age of fourteen, which entitled him, according to the laws of the country, to have a share in the government, she caused him to be poisoned.

Immediately on the murder of Cæsar, she declared for the triumvirs Antony, Lepidus, and Octavius, who had formed a combination avowedly to avenge his death. After the battle of Philippi, which extinguished the hopes of the patriots of Rome, Antony went into Cilicia to settle the affairs of that province. Here he summoned the queen of Egypt to appear before him, on account of some charge which had been advanced against her. She readily obeyed the summons, and set out confident of enslaving her judge. Never had any thing been seen equal to the apparatus of pleasure, with which she approached the devoted Antony, who might fairly date his ruin from that interview. Having provided herself with magnificent presents, vast sums of money, and the most sumptuous dresses, she embarked on board a vessel which was gilt all over, with purple sails and oars plated with silver. She was seated under a canopy of cloth of gold, in the same dress and attitude in which Venus was usually represented, with a number of comely youths fanning her like Cupids, and beautiful virgins representing *Nereids* and *Graces*. The hills re-echoed with the sounds of various instruments, and the oars keeping time with the music, doubled the harmony. Such quantities of valuable spices were burnt on the deck, that the air to a great distance was filled with fragrance.

Antony was at that time sitting in judgment; but his tribunal was instantly deserted, and he was left in the midst of his lictors. The whole city flocked to see this work of enchantment, and flattery mixing itself with the public astonishment, spread the report, that Venus was come on a visit to Bacchus, (designations tolerably characteristic of the parties,) to consult about the welfare of Asia. The triumph of the Egyptian queen was as rapid and as complete as the memorable victory of Cæsar. *She came, saw, and conquered.* The complaints, which had been made against her, were forgotten in the fascinations of her conversation, and the attractions of her person; and Antony drunk the delicious poison, till he neither had power nor inclination to snatch himself from the witchery of her charms. He could deny her nothing, however repugnant it might be to humanity, justice, or religion. *Plut. in Ant.*

At her request, assassins were sent to dispatch her sister Arsinoe, who murdered her in the temple in which she had taken refuge. To preserve Antony within her toils, she kept him in a constant intoxication of various pleasures, to which he had always been prone, though till then he had been capable of great energy and judgment, when roused into activity by the pressure of circumstances. At one of her entertainments, Antony expressing his astonishment at the vast number of golden cups and vessels adorned with jewels, she immediately ordered her servants to carry them all to his house as a present. She wore in her ears two pendants of pearl, the largest that had ever been seen, each of them worth fifty-two thousand pounds of our money. Pliny informs us, that, on a certain occasion, she took one from her ear, and, having dissolved it in vinegar, swallowed it, to show how much she could afford to spend on one draught. She was going to do the same with the other, when Plancus prevented her, and saved the pearl, which was afterwards carried to Rome by Augustus, and, being cut in two, was formed into pendants for the Julian Venus.

One is apt to be astonished at the boundless profusion of this woman, and to wonder that she should make such efforts to please Antony, when her personal charms so readily ensured her conquest. But all this extravagance was not thrown away; she was buying provinces and kingdoms: and the liberality, or rather the madness of Antony, soon reimbursed her for all the wealth she had expended to please him.

Antony being obliged, by the state of his affairs, to leave Tarsus, Cleopatra, having accompanied him as far as Tyre, there took leave of him, and returned into Egypt. But he could no longer exist without her; having therefore entrusted his affairs to his lieutenants, and deserted the plans which he had in view, he followed her forthwith into Egypt, where they spent the winter together in the most disgraceful revelry and dissipation. Whilst Antony was thus wasting his time in folly, Octavianus was daily strengthening his interests in Italy, without any one to oppose him, except Fulvia, the wife of Antony, a woman of masculine spirit, who, notwithstanding her husband's infidelity, exerted herself in securing a powerful party in Rome. Antony found it necessary to attend to his interests in that quarter, and sailed towards Italy with two hundred ships, with the intention of making war on his opponent. His wife met him by the way, but he treated her with the utmost neglect, and instead of commending her zeal, blamed her for exciting unnecessary commotions. His cruelty and infidelity broke her heart: and, on her death, a match was proposed between Antony and Octavia, the sister of Octavianus, with a view to cement the existing differences. Octavia was a woman of extraordinary merit, and Antony's friends entertained the hope that she would completely detach him from Cleopatra, as that connection was universally considered as disgraceful, and was plainly foreseen to be pernicious in its consequences. But having spent a single winter with Octavia at Athens, he hastened back to the scene of his former pleasures, and devoted himself more absolutely than ever to the charms of Cleopatra. As Antony was an excellent officer, he had an ambition common to all the great Roman commanders, of conquering the Parthians. Having made great preparations, he set out for this difficult expedition: but contrary to the advice of all his officers, he sent for Cleopatra to join him in Syria. The delay which her presence occasioned, ensured the failure of an enterprise which, when undertaken by other commanders, even under the most auspicious circumstances, had never proved successful; and Antony's hurry to rejoin Cleopatra, nearly completed the destruction of the Roman army; for he lost sixty thousand men, chiefly by forced marches over the mountains of Armenia, at that time covered with snow.

The fortunes of Antony and Cleopatra, from this period, became so inseparably connected, that their history must be joined, though we should be forced to repeat some circumstances mentioned in a former article of our work. Previously to Antony's setting out a second time against the Parthians, he bestowed on Cleopatra Cyrene, Cyprus, Cœlo-Syria, Sturea, and Phenicia, with a great part of Cilicia and Crete. Having taken Artabazes, King of Armenia, prisoner, contrary to the most solemn oaths and promises, he entered Alexandria in triumph, which gave great offence to the Romans, as they regarded a triumph as peculiar to the city of Rome.

The measure of Antony's follies was now nearly complete: he ordered Cleopatra to assume the name of Isis, whilst he took that of Osiris, and after that they always affected to appear in public in the dress peculiar to these deities.

Octavianus artfully improved all these follies to his own advantage, and the Roman people became at last so exasperated, that he sought only a fair opportunity of declaring war. With this view he sent his sister Octavia to join her husband, intending to make his rejection of her, which he anticipated, the ground of an open quarrel. This produced the effect intended: as soon as Cleopatra heard of her approach, (for she had arrived at Athens on her way to Syria), she affected the utmost despondency, that she might make Antony believe she was dying of love for him. She shed tears, that he might see her distress, and pretended to wipe them away in haste, as if she wished to conceal them and prevent him from being sharer in her pain. These artifices succeeded, and Octavia was ordered back to Rome.

These, with other causes of grievance, completed the rupture between Antony and his rival; and each party now began to prepare vigorously for war. Antony and Cleopatra hastened to Ephesus, where eight hundred vessels were collected to support his cause. His friends now represented the necessity of sending home Cleopatra, to wait the event of the war. But she, afraid of an accommodation between the two rivals, and of her own exclusion from the affections of Antony by the reception of Octavia, used every effort to defeat this measure, and at last succeeded in bribing Canidius, one of Antony's chief advisers, to recommend her continuance with the army. She now became jealous of all his friends, and was constantly employed either in undermining their influence, or in endeavouring to drive them from his presence, by the imperious haughtiness of her manners. In this she succeeded so well, that many of his principal friends, disgusted with her conduct, and afraid for their safety under such dangerous influence, openly went over to the side of Octavianus. This wily politician conducted himself in the whole of this affair with his usual address: finding himself prepared for declaring war, it was proclaimed, not against Antony, but against Cleopatra, as having bewitched him with charms and potions, so as to deprive him of his senses, and make him compromise the dignity of the Roman people.

At last the armies of the two contending parties were drawn up on opposite sides of the Ambracian Gulf: their fleets covered the sea between; and the result of victory was to be the empire of the world. But here the evil genius of Antony finally prevailed: contrary to the advice of his most experienced officers, and contrary to the conviction of his own mind, he listened to the arguments of Cleopatra, who had an eye to her own escape in case of discomfiture, and ventured to commit his fortunes to the issue of a sea fight. The Egyptian queen, who advised the measure, was the chief cause of its failure. She became terrified at the noise of the fight, and fled, with sixty large ships, before she was in the smallest danger. Antony, like a person deprived of reason, immediately followed her, and by his flight decided the fate of the battle, which till that time had been doubtful. He was sensible that he had lost every thing by her misconduct, and for some time refused to see her; but they were soon reconciled by the interference of her maids, and he became her devoted slave as much as ever. Cleopatra, suspecting that her subjects might not receive her, were her disgrace and misfortunes known, entered the harbour of Alexandria with crowns and garlands on the prows of her ships, as if she had been returning from a victory: being thus admitted into the town, she immediately put to death all whom she suspected of disaffection to her person or government.

She now engaged in a very extraordinary enterprize, which perhaps indicated more energy than judgment. Convinced that Octavianus would pursue her into Egypt, and sensible that she possessed no means of resistance, she ordered all her ships to be carried from the Mediterranean into the Red Sea, across the isthmus of Suez, a distance of about seventy miles. Her object was to forsake Egypt, and go in search of some new settlement. The Arabs, however, at the instigation of one of Octavianus's lieutenants, burnt all the ships that were carried over, as well as those that were in the Red Sea before, and the queen was obliged to desist from this romantic undertaking.

Nothing now remained but to await the approach of the conqueror. Antony and Cleopatra sent the most submissive proposals to Octavianus, offering to live a private life at Athens, provided the crown of Egypt were reserved for Cleopatra's children. This proposal was rejected: Cleopatra's ambassadors, however, were instructed by their mistress to treat privately for her own safety: as Octavianus was extremely anxious to get hold of her person, to adorn his triumph, and of her treasures, to defray the expences of the war, he dismissed the ambassadors with many fair words and promises of kind intentions towards their mistress, provided she would kill Antony, who was represented as the cause of all her misfortunes. This she positively refused to do; but engaged to do what amounted to the same thing, to deliver him and her kingdom into the hands of Octavianus.

In conformity with this engagement, Pelusium, the key of Egypt on the east, was delivered into his hands without resistance, though it was capable of sustaining a long siege. Antony was at this time employed on the opposite frontier; and hearing of the rapid approach of the Roman army towards Alexandria, he hastened to the defence of the city. Cleopatra in the meantime, to prevent Antony from suspecting any understanding between her and Octavianus, had retired into a high tower, where she collected her most valuable treasures, and materials for a funeral pile, giving it out, that she intended to consume herself and her treasures together, should the town fall into the hands of the enemy. Antony, with that impetuosity which distinguished him in war, sallied out from the city, and falling unexpectedly on the cavalry of the enemy defeated them with great slaughter.

Encouraged by this success, he prepared next day to engage their fleet; but no sooner was the signal given, than Cleopatra's admiral, in compliance with her orders, went over to the enemy. Antony then hastened to his land forces, but found to his astonishment that they had all to a man deserted to Octavianus. His eyes were now opened to the perfidy of Cleopatra, whom, till that moment, all the remonstrances of his friends could never induce him to suspect, and he flew to her palace in a paroxysm of rage and despair to put her to death. She saved herself by a timely flight, and took refuge with two of her maids in her inaccessible tower.

She now caused it to be given out that she had killed herself, to avoid falling into the hands of the enemy; and Antony believing the tale, instantly passed from the extreme of resentment to that of tenderness, and, in his despair, fell upon his sword, inflicting a wound which occasioned his death.

As soon as Cleopatra heard of this tragical event, all her affection revived for a man whom her counsels had ruined, and at last her perfidy betrayed; and learning that he was not yet quite dead, she ordered him to be raised up to her apartment in the tower, by means of pullies which happened to be there at the time, for the purpose of raising stones to the top of the monument. He was raised with difficulty by herself and her two maids, as she refused to open the gate to receive assistance from below. She received him bathed in blood, and had the melancholy satisfaction of seeing him expire in her arms.

At the moment that Antony breathed his last, Proculeius arrived from the camp of Octavianus, requiring Cleopatra, with many fair promises, to surrender her person. This, however, she obstinately refused to do, except on such terms as Octavianus was determined not to grant; for his great ambition was to have such a celebrated personage to adorn his triumph, whilst she viewed this consummation of her sufferings with the greatest horror. To prevent her from taking any desperate step, Octavianus sent Cornelius Gallus, a man of great honour and eloquence, to converse with her. Whilst he was amusing her with fair speeches at the gate of the monument, Proculeius with two servants scaled the wall, and hastened down to secure her person. As soon as she saw herself within their power, she drew a dagger, which she always carried about her, and attempted to stab herself. But Proculeius springing forward, seized her in his arms, and wrested the dagger from her hands.

Octavianus was overjoyed at this acquisition. He ordered her to be watched with the strictest care, and at the same time to be treated with the greatest respect. He sent to her to know, if there was any favour which she had to ask. All that she requested was, that she might be permitted to bury Antony. This was readily granted;

and Antony's body was deposited, with every circumstance of funeral magnificence, in the burying-place of the kings of Egypt. Her grief and her exertions on this occasion brought on a fever, and, with the consent of her physicians, she resolved to abstain from food, and starve herself to death. This design being discovered, she was placed under the care of other physicians, and was induced by threats and promises to follow their prescriptions.

After she was pretty well recovered, Octavianus sent to her, requesting an interview. She was delighted with this proposal, and prepared to play off all her arts, and all her charms, against her conqueror. But the cold-blooded politician, though he was afterwards sufficiently notorious for his gallantries, had at present a different game to play; he therefore kept his eyes fixed upon the ground during the whole conversation, and it was perhaps not the least of Cleopatra's mortifications, that she had now probably for the first time fruitlessly displayed her charms. She still, however, entertained the hopes, that she might avoid the ignominy of being led in triumph: and with this view offered to give up all her moveables, treasures, and jewels; but Octavianus was determined that nothing should redeem her from this dreaded humiliation. But Cleopatra had succeeded better with Cornelius Dollabella, one of Octavianus's intimate friends. This Roman was desperately in love with her; and had engaged to give her timely intimation of his master's intentions: Accordingly he sent her word, that in three days she and her children were to be put on board a vessel, and conveyed to Rome. This determined her to put in execution the purpose which she had long formed, in contemplation of this event.

Finding it difficult to elude the vigilance of Epaphroditus, who was appointed to watch her, she made a great entertainment, affected unusual gaiety, and in the midst of the general mirth, rose from table, and wrote a letter to Octavianus, which she requested Epaphroditus to deliver into his own hands, as it contained matters of importance. As soon as he was gone, she withdrew with two of her maids, and calling for a basket of figs, which one of her servants had brought in the disguise of a peasant, she applied to her arm an asp which was purposely concealed among the figs. This is the common account; but Plutarch, *in Anton.* says, that she had collected the poison beforehand, and introduced it into her arm, by tearing her flesh with her teeth. She soon expired, in the arms of her maids. In her letter to Octavianus, she requested to be buried in the same tomb with Antony: this leading him to suspect her intentions, he instantly dispatched some of his friends to prevent her attempt. They found her lying dead, on a golden bed, in her royal robes, with one of her maids likewise dead, and the other expiring beside her.

Thus ended the life of this celebrated queen, whose adventures are more like the fictions of romance, than the ordinary details of history. In her ended the line of Ptolemy Lagus, the founder of the Greek dynasty in Egypt, whose family had reigned from the death of Alexander, till its extinction in Cleopatra, 294 years. It is agreed on all hands, that she was very beautiful, very accomplished, and very unprincipled. Chastity was not a virtue that she aspired to, and her libertinism was too much even for an age, in which more than an ordinary degree of profligacy was readily tolerated. And yet she generally bestowed her heart, where she surrendered her person, and continued to retain a tenderness for those who had once been the objects of her affection. Wonderful things are told of her acquirements in point of language; and it is affirmed that she could converse with Ethiopians, Troglodytes, Jews, Arabians, Cyrians, Medes, and Persians, without an interpreter, and with as much ease, as if she had been a native of the countries whose language she adopted. Her death was a great disappointment to Octavianus, who caused her image to be led in triumph, since he could not obtain her person. Horace celebrates her death as a great piece of heroism.

Ausa et jacentem visere regiam
Vultu sereno fortis, et asperas
Tractare serpentes, ut atrum
Corpore combiberet venenum,
Deliberata morte ferocior;
Sævis Liburnis scilicet invidens
Privata deduci superbo
Non humilis mulier triumpho.

Hor. Carm. lib. i. Od. 37.

CLEPSYDRA. See Hydrodynamics.

CLERMONT Ferrand, *Augustonemetum* and *Arverni Claramons*, a city of France, and capital of the department of the Puy-de-Dome, is situated on a small eminence, at the foot of a lofty mountain between two small rivers, one of which is called the Artier. The streets are narrow, and the houses gloomy, but the promenades and public places are superb. Before the great altar of the cathedral there is a fine ancient sarcophagus. The principal articles of manufacture in this city are, fine rateens, coarse serges, druggets, linen cloth, ribbands, silk stockings, candles, and paper. The preserved apricots of Clermont have been long celebrated; the cheese made in the neighbourhood, known by the name of the cheese of Auvergne, is reckoned particularly excellent. Within an enclosure in the city, there is a petrifying spring, which has deposited across a garden, in the direction of its course, a wall 140 feet long, and in some places from 15 to 20 feet high. This brook is also said to have petrified a wooden bridge so completely, that carriages can pass over it. The town of Montferrand, from which Clermont receives the addition to its name, forms one of the fauxbourgs of the city. Population 24,478. In the *Almanac du Commerce* for 1811, it is stated at 30,000. East Long. 3° 5′ 17″, North Lat. 45° 46′ 44.″ (w)

CLERODENDRUM, a genus of plants of the class Didynamia, and order Angiospermia. See Botany, p. 255.

CLETHRA, a genus of plants of the class Decandria, and order Monogynia. See Botany, p. 211.

CLEVES, the *Clivia* of the ancients, is a town of France, in the department of the Roer, and formerly was the capital of a duchy of the same name, in the circle of Westphalia. It is situated on the brow of a hill, upon the canal of Spoy, about two miles from its communication with the Rhine. The town, which consists of several irregular streets, is divided into the higher and the lower, is well built, and contains about 800 houses. It is surrounded with walls, but is not strongly fortified. There is here a church and three convents. The Lutherans, the Calvinists, and Memnonites, have likewise each a church, and the Jews have a synagogue. In the higher part of the town is an ancient castle, called the *Tour du Cygne*, which, as the inhabitants pretend, was built about 300 years before Christ, and from the top of which 24 towns can be seen. The declivity of the eminence on which it stands, is cut into terraces and walls so as to form a delightful English garden. The principal manufactures of the place are silk stuffs, draps, linen cloths, and tobacco. Population 4243. East Long. 6° 7′ 6″, and North Lat. 51° 47′ 40″. (w)

CLEVES and Berg, Grand Duchy of, is the name of a new grand duchy, formed out of the old duchy of

Cleves, another part of which is added to the French empire, and is comprehended in the department of the Roer.

The Grand Duchy of Cleves and Berg is divided into four departments, as follows:

Departments.	Principal towns.	Population.
Of the Rhine,	Dusseldorff, ...	322,284
Of the Sieg, .	Dillembourg, ...	133,070
Of the Rurh,	Dortmund, ...	212,602
Of the Ems, .	Munster, ...	210,201
	Total population	878,157

The principal productions of the duchy are wood, lint, grain, and fruits of all kinds, cattle, and mines of coal, iron, lead, mercury, copper, and calamine. Napoleon Louis, born 11th October 1804, is Grand Duke of Cleves and Berg. See Roer. (*)

CLITORIA, a genus of plants of the class Diadelphia, and order Decandria. See Botany, p. 283.

CLOCK. See Horology.

CLOISTER. See Monastery.

CLODIUS. See Cicero, vol. vi. p. 469.

CLONMACNOISE. See King's-County.

CLONMELL, a market and post town of Ireland, in the county of Tipperary. It is situated at the extremity of the county, on the banks of the river Suire, which is navigable up to the town for large boats, and the tide flows a little above Clonmell. The principal public buildings are the court-house and the jail; the former, in which the assizes are held, is a new and handsome building, and the latter has also been recently built upon Mr Howard's plan. The woollen and cotton manufactures formerly flourished in this place, but they have now greatly declined. There is here an immense establishment for pickling bacon. No fewer than 1200 hogs are annually slaughtered and cured with Liverpool salt. The warehouse, which will hold 100 tons, is paved with flags, and has kennels which convey the pickle into a cistern in its centre. The introduction of the English breed has been found highly advantageous, as it produces much less offal, which brings only one guinea per cwt. The bacon is not dried here, but is sent to England in a pickled state, packed up in cloths. Clonmell carries on a very considerable import trade for the supply of the interior parts of the county. The principal exports are corn and pork. There are two bankers in Clonmell, who circulate notes to the amount of £200,000. The catholics have here a chapel, school, and friary, the ground rent of which Mr Bagwell remits, besides a large poorhouse to which £500 is annually contributed by the county. The burgh is a close corporation under the influence of Mr Bagwell. West Long. 7° 43′, North Lat. 52° 21′. See Wakefield's *Statistical and Political Account of Ireland.* (*w*)

CLOSE *Intervals*, in music or close harmony, are such notes in a chord as lie near to each other. Dr Robert Smith, in his *Harmonics*, prop. 22. cor. 4. says, that "the harmony of a concert will be smoother and distincter, and generally more pleasing, for taking the chords of the thorough bass as near as can be to the bass notes, and no more of them than are necessary, and those few upon the softer and simpler stops of an organ of the common construction; because the beats will then be fewer, slower, and softer, and so the voices and other instruments will appear to greater advantage." On the other hand, Dr Burney says, that "organists have long observed, that close intervals in the bass, though consonant, are disagreeable, and never, in full playing, give the third in a common chord, with the left hand on the bass." Mr Holden, speaking of the minor common chord, *Essay*, p. 124. says, that the third had better not to be hard at all, but the chord be given thus, $\begin{matrix}\mathrm{XVII}\\ \mathrm{V}\\ \mathrm{VIII}\\ \mathrm{I}\end{matrix}$.

The principles on which this gentleman reasons, are, however, some of them so erroneous, as will appear in our article Grave *Harmonics*, that little reliance can be placed on his opinion, towards deciding between the opinions of Dr Smith and Dr Burney respecting close intervals. (*c*)

CLOTAIRE. See France.

CLOTH MANUFACTURE.

Cloth is a term in the English language, particularly applied to the woollen manufacture; but in its more comprehensive and general acceptation, it may be understood to signify any substance produced by the interweaving of animal or vegetable filaments. The cloth made in the islands of the South Sea, from the descriptions of Captain Cook and other circumnavigators, and from the specimens which have been brought to Europe, appears indeed, in general, to be produced rather by cohesion of the parts than texture; but this assimilates it more to the ideas which we attach to paper or pasteboard, than to those which we form of cloth. Almost all the cloth which is known or used in Europe, is composed either of the animal substances, wool and silk, or of the vegetables, flax and cotton. For some purposes, indeed, hair is spun into thread, and woven into cloth; and the finer and more ductile metals, gold and silver, are also occasionally spun along with silk, for some of the richer species of ornamental texture.

History of weaving.

With the antiquity of weaving we are neither much acquainted, nor, however amusing such knowledge might be to the antiquarian, is this loss greatly to be regretted. That the art was brought to considerable perfection in very early ages, is sufficiently obvious, both from sacred and profane history. There seems also little doubt that it is of Asiatic origin, and has only gradually extended to the western parts of Europe. We have the authority of Julius Cæsar, that, when he invaded Britain, it was totally unknown; and the many public acts relative to the woollen manufacture in the earlier period of English history, evidently prove, that the greater part of our wool was, for a very long series of years, exported in a raw state, and manufactured upon the continent. The cruelties and atrocities of the Duke of Alva, in 1567, and the subsequent persecutions attendant on the revocation of the edict of Nantz by Louis XIV. are assigned, by historians, as the causes which gave to Britain the knowledge and ingenuity of foreign artizans, and permanently founded the woollen and linen manufactures, the former of which has become the acknowledged staple of England, and the latter of Ireland. The much more recent invention of Sir Richard Arkwright, has introduced the very extensive manufacture of cotton, and added a lucrative and elegant branch of traffic, the lighter and fanciful department of which has become, in some measure, the staple manufacture of Scotland, whilst the more substantial and durable fabrics have added to England a manufacture, inferior, in importance and extent, only to the woollen.

The process of manufacture of all these descriptions of cloth, from the raw to the finished or marketable state, may be divided into three great stages of manufacture.

1st, The preparatory processes which the raw material undergoes to bring it into that state in which it is fit to assume the appearance of cloth, or what is generally understood by the term *yarn*. For the account which we have to lay before our readers of these operations, we must refer them to the respective articles COTTON, FLAX, SPINNING, WOOL, SILK, &c.

2d, The operations by which the materials are brought from the state of yarn into that of cloth, which is properly the subject of this article, but which we can here only treat in a general way; for the different kinds are so numerous and varied, that we must refer much of the peculiarities to the articles which will be found under the respective titles or names, by which various kinds of cloths or stuffs are known.

3d, The processes which cloth undergoes, after coming out of the weavers hands, to fit it for the market; and which we must also refer to the various articles BLEACHING, DYEING, PRINTING, CALENDER, GLAZING, and many others.

In general, we may remark, that the great requisites in every species of cloth, from the heaviest to the lightest fabrics, are durability, warmth, and beauty. For those kinds which compose the household furniture and dress of the generality of mankind, the first and second are the most essential; and for the ornamental kinds, which furnish show and splendour to the drapery of the opulent and luxurious, the latter is almost the only quality ever required.

On the fabric of cloth.

Previous to entering into any detail of other particulars, we shall lay before our readers such general remarks as occur upon what is termed the *fabric* of cloth; a matter which we conceive to be not only of the most essential importance, but which has been most unaccountably neglected, even by those who practise the manufacture, and who, with very few exceptions, regulate their operations in this respect by no fixed or determinate rule, but generally are contented merely to copy what they are taught, without any other guide to detect error, than actual experience, which very frequently is dearly purchased. Yet we conceive it possible, that this important point may be reduced to such a degree of mathematical precision, as might render it capable of conclusive demonstration, or at least that the approximation may be so near, as to guard the person who will be at pains to adopt it, from almost the slightest danger of great error, even in regulating the fabric of any species of cloth to which he has not been previously accustomed. For the better understanding of this method, it may be necessary to consider, very briefly, that quality of yarn, which is called its *grist* or fineness.

If a thread of yarn be considered as a cylinder, its weight must be in the compound ratio of its magnitude and density. Now, yarn being made up in hanks of a determinate length, this length may be considered as the altitude of the cylinder, and consequently its *grist* or fineness is the area of the base; and then as the areas of cylinders are in proportion to their circumscribing squares, the square root of the square will be equal to the diameter of the base. When yarn of any kind is warped, and stretched in a loom, to undergo the subsequent operation of being woven into cloth, the threads which compose the warp are parallel to each other, and their parallel situation is preserved by the utensil called the *reed*, through the intervals between the divisions of which a certain number of threads pass. The number of divisions in this reed, therefore, ascertains the number of threads of warp which are to be woven into cloth of any determinate breadth. Now the breadth of every thread or cylinder being the diameter of its base, and the reed being the scale which regulates the number of these threads in a given measure, the ratio which the one bears to the other ascertains the number of threads, and their contiguity to each other in the cloth. Let then the square root of the mass in any determinate length of yarn be taken as the measure of the diameter of the base of a thread, and let the number of the reed which will form a proper fabric be known, and any other will be found to form a similar fabric. From this arises a very simple analogy or proportion, which may be thus stated: Let the weight of one kind of yarn be expressed by a, and that of another by b. Let a be properly woven in a reed or scale, which contains 1200 intervals or divisions in 37 inches, which is the common measure of the linen reed. Then to ascertain the proper reed for b, the proportion will be as $\sqrt{a}$ is to 1200 so is $\sqrt{b}$ to the reed required. Hence as a is to 144, so is b to the square of the reed required. Suppose now that a represents cotton yarn No. 60, and b represents No. 100, then

As 60 : 144 : : 100 : 14,400, the root being 15.49 *nearly*, which is the answer. From this the following simple arithmetical proportion will arise for practical use.

1st, If the yarn is known, and the number of the reed wanted,

As the name or designation of the first yarn given
To the square of the given reed,
So is the name or designation of the second yarn
To the square of the reed required.

2d, If, as before, the yarn and reed are known, and the yarn wanted to fit any other reed,

As the square of the given reed
To the yarn,
So is the square of the other reed
To the yarn required.

In actual practice, the following objection, which is very plausible, will readily occur to practical manufacturers, and, at first sight, will probably induce almost the whole of them to reject these rules as erroneous and inconclusive. They will assert, and with truth, that a manufacturer who would implicitly adopt and follow these rules, would either make all his fine goods so dense and heavy in the fabric as to disgust his customers, or that his course goods would be so flimsy in the texture, as to be totally useless. To this it is only necessary to reply, that it arises from no error in the calculation, nor want of truth in the general principle, but in what was premised as a general requisite in cloth at the outset;

namely, that *durability* and thickness is the first object in coarse goods, and beauty and transparency in fine. It would afford but a slender recommendation to a birth-day dress, to possess that warmth and durability which would form the chief excellence of a watch-coat, or blanket; and it would be equally useless, to give to the coarse manufacture, which is valuable in proportion to the shelter which it affords from the inclemency of wind and weather, qualities which could only afford gratification to the eye, by the sacrifice of every comfort.

The warp of a web being longitudinally stretched in parallel straight lines, and the woof or waft being inserted at right angles to it, the substance produced as cloth, will bear a strong analogy to the form of a raft of wood, consisting of two platforms of square beams, laid across each other and fastened together; or if we suppose that a number of cylindrical pieces of wood, such as the topmasts or yards of a ship, are laid parallel to each other, and that cords or ropes are interwoven between them to keep them together, we shall have a very exact representation of a piece of cloth, on a scale of such magnitude as will admit of all the proof of actual measurement. In cloth, even of the finest kinds, the length, breadth, and number of the component threads or cylinders, in the piece, may be ascertained with equal precision; but, from the smallness of the diameter of every thread, it becomes impossible to measure them *actually*, with any degree of accuracy. The length and the weight or mass, however, being known, the diameter may be found by a calculation, which bears evident marks of great exactness, and we may then safely assume that no difference can arise, provided the densities of all threads are the same. Upon this point, however, there has been some difference of opinion, and the subject has been so little investigated in a scientific manner, that it would be perhaps presumptuous to draw any absolute conclusion upon the subject. We shall therefore only observe, that the argument upon which the increase of density in fine yarn above coarse chiefly rests, is this, that in spinning fine yarn, a greater number of revolutions of the wheel are necessary to give the twist sufficiently to produce a sufficient cohesion of the fibres, than in coarse. This is incontrovertibly true; and as the filaments or fibres, by this twisting, assume the form of a screw or spiral, the point to be decided is, simply whether, by this excess of twisting, the fibres of fine yarn are not brought more closely into contact than those of coarse; and consequently that the diameter of the thread is diminished in the same proportion that the twisting is increased. It must be obvious, that where the circumference exposes a small surface, many more revolutions will be required than where it presents a large one, before all the fibres can be sufficiently stretched; and, consequently, that fine yarn will always require more twisting than coarse to give it the same tenacity. But as every thread from the stoutest cable to the finest which human art and industry can produce, contracts *in length*, by the operation of twisting, there seems reason enough to conclude, that the compressing power exerted, acts either entirely upon the length, or that what is exerted on the diameter, must bear a very small proportion indeed to the other. We may therefore infer, that the nearest approximation to actual truth, will be to consider a rope or thread like any other solid cylinder, and that the difference of density will not very materially affect the calculation. Upon this principle we shall easily arrive at a very considerable degree of mathematical precision, and upon the whole come nearer to actual truth, than by any other hypothesis yet known.

In Plate CXCIII. will be found some figures, explanatory of what further remarks may be necessary on this subject as connected with *fabric*; and it will also be useful in conveying correct ideas of the varieties of texture most generally used, both in the substantial and flimsy descriptions of woven goods.

Plate CXCIII. Fig. 1.

Figure 1st of Plate CXCIII. may be supposed to represent any solid body composed of various parts, *lashed* together. If the darkened squares are so many parallel beams of wood, connected by cordage, we arrive at once at a precise idea of texture. The length of these beams is known by measurement; the breadth of the whole consists of the aggregate number of pieces of wood, added to the space which the cords occupy between each, and which will be more or less, in proportion to the thickness or diameter of these cords. It is also obvious, that it is impossible to bring the beams into actual contact; for were we to suppose that the connecting or lashing cords were actually as fine as human hairs, they must still occupy some portion of space. The thickness, it is equally apparent, is that of one beam and one cord; but if we suppose the cords everywhere in actual contact, we may then also suppose that the thickness is that of the beam and two cords. Now, it is hardly possible to conceive, that in a flexible substance, such as those used in the fabrication of cloth, any means could be devised, to bring every thread of woof into actual contact, so as to cover the warp both above and below. We may therefore very safely assume, as a general principle, that the geometrical thickness of cloth, is the measure of the diameter of one thread of the warp, added to the measure of the diameter of one thread of the woof; and that when those measures are equal, the thickness of the cloth is, of course, double the diameter of one of the threads of which it is composed. Thus we have the utmost thickness of fabric of which cloth is capable, and more than even the strongest canvass, with which we are acquainted, can possess. Indeed a fabric of this kind, were it even easily attainable, would be practically useless; for the immense increase of density, would so completely take away every degree of pliancy and flexibility, that the fabric would be as unsuitable for any purpose to which cloth is properly applicable, as a fir plank, or a sheet of copper.

Plate CXCIII. Fig. 2.

In Plate CXCIII. Fig. 2. is a representation of a section of cloth of an open fabric, where the round dots which represent the warp, are placed at a considerable distance from each other. In this figure we see very evidently, that the geometrical thickness of cloth may be considered in the duplicate ratio of the diameter of one thread; for if we suppose the two parallel lines which bound the figure, to represent two boards used in the calender press where the cloth is finished, and that they are to be pressed together by any mechanical power, we shall at once see that their effect must immediately flatten the threads, and divest them of their cylindrical form.

Plate CXCIII. Fig. 3.

Fig. 3. of Plate CXCIII. may be supposed a plain fabric of that description, which approaches the most nearly to any idea we can form of the most dense or close contact of which yarn can be made susceptible. Here the warp is supposed to be so tightly stretched in the loom, as to retain entirely the parallel state without any curve or flexure whatever, and the whole is therefore necessarily given to the woof. This mode of weaving can never really exist; but if the warp be sufficiently strong to bear any tight stretching, and the woof be spun very soft and flexible, something very near it may be produced. This way of making cloth is well fitted for those goods which require to give considerable warmth, but they are sometimes the means of very gross fraud and imposition; for if the warp is made of very slender threads, and the woof of slackly twisted cotton or woollen yarn, where the fibrils of the stuff, being but slightly brought into contact, are rough and oosy, a great appearance of thickness and strength may be given to the eye, when the cloth is absolutely so flimsy, that it may be torn asunder as easily as a sheet of writing paper. Many frauds of this kind are practised. A very common one is in a kind of fanciful stuff which used to be hawked about the streets of London, and most of the large towns of Britain, especially the sea-ports, by a set of men habited like sailors. These stuffs were composed of very fine silk warp, and very slackly twisted cotton woof, perhaps eight or ten times coarser than the warp: the silk of course entirely disappeared, and the semblance of a very strong fabric of cotton was presented, and sold *apparently* cheap, under the pretence of being smuggled home in an East Indiaman. Strength, beauty, and cheapness, were thus apparently united, and the unwary purchaser, whilst enjoying the triple pleasure of having profitably expended his money, procured a desirable acquisition, and outwitted all the precautions which either the government or directors could take, found, to his infinite astonishment and vexation, upon the first application of the finger and thumb, that his purchase, which was generally extolled by the vender, for being *as tough as the mainsail of a seventy-four*, proved as weak as a cob-web. The impostor generally added to the fraud, by pulling the cloth apparently with great force in that direction in which the coarse woof gave the resistance, but cautiously avoided even a touch against the warp, which would at once have detected the fraud.

In Fig. 4. Plate CXCIII. is given a representation of the position of a fabric of cloth in section, as it is in the loom before the warp has been closed upon the woof, which still appears as a straight line. This figure may usefully illustrate the direction and ratio of contraction, which must unavoidably take place in every kind of cloth, in a greater or smaller degree, according to the density of the texture, the dimensions of the threads, and the description of the cloth. Let AB represent one thread of woof completely stretched by the velocity of the shuttle in passing between the threads of warp which are represented by the round dots 1, 2, &c. and those distinguished by 8, 9, &c. When these threads are closed by the operation of the heddles to form the intertexture, the first tendency will be to move in the direction 1 *b*, 2 *b*, &c. for those above, and in that of 8*a*, 9*a*, &c. for those below; but the contraction of AB, by its deviation from a straight to a curved line, in consequence of the compression of the warp threads 1 *b*, 2 *b*, &c. and 1 *a*, 2 *a*, &c. in closing, will produce, by the action of the two powers at right angles to each other, the oblique or diagonal direction denoted by the lines 1, 8—2, 9 to the right, for the threads above; and that expressed by the lines 2, 8—3, 9, &c. to the left, for the threads below. Now, as the whole deviation is produced by the flexure of the thread AB, if A is supposed to be placed at the middle of the cloth, equidistant from the two extremities, or *selviges* as they are called by weavers, the thread at 1 may be supposed to move really in the direction 1 *b*, and all the others to approach to it in the directions represented, whilst those to the left would approach in the same ratio, but the line of approximation would be inverted. By pursuing this plan, which, as far as the writer of this article knows, is totally new, the theory of fabric might be reduced to a very great degree of certainty; and here a field is entirely open for the researches of an expert geometrician, to apply the principles of his science to the most extensive and useful manufacture, not only of this country, but of every other.

Plate CXCIII. Fig. 4.

Fig. 5.

Fig. 5. represents that common fabric used for lawns, muslins, and the middle kind of goods, the excellence of which neither consists in the greatest strength, nor in the greatest transparency. It is entirely a medium between Fig. 2. and Fig. 3. Its principles are in every respect similar to those already noticed.

In the efforts to give great strength and thickness to cloth, it will be obvious, that the common mode of weaving by constant intersection of warp and woof, although it may be perhaps the best which can be devised for the former, presents invincible obstructions to the latter beyond a certain limit. To remedy this, two modes of weaving are in common use, which, while they add to the power of compressing a great quantity of materials in a small compass, possess the additional advantage of affording much facility for adding ornament to the superficies of the fabric. The first of these is double cloth, or two webs woven together, and joined by the operation. This is chiefly used for carpets; and its geometrical principles are entirely the same as those of plain cloth, supposing two webs to be sewed together. A section of the cloth will be found in Fig. 6, Plate CXCIII.; and what further relates to this part of the subject, in the article Carpet.

Plate CXCIII. Fig. 6.

Of the simplest kind of tweeled fabrics, a section is given in Fig. 7, Plate CXCIII.; and as this is a most important branch of the cloth manufacture, it may be proper to consider it with some attention.

Plate CXCIII. Fig. 7.

The great and prominent advantage of the tweeled fabric in point of texture, arises from the facility with which a very great quantity of materials may be put closely together. In the figures, the warp is represented by the dots in the same straight line as in the plain fabrics; but if we consider the direction and ratio of contraction, upon principles similar to those laid down in the explanation given of Fig. 4, Plate CXCIII. we shall readily discover the very different way in which the tweeled fabric is affected.

Thus we see by the Figure, that when the dotted lines are drawn at *a b c d*, their direction of contraction, instead of being upon every second or alternate thread, is only upon every fifth thread, and the natural tendency would consequently be to bring the whole into the form represented by the lines and dotted circles at *a b c d*. In point then of thickness, from the upper to the under superficies, it is evident, that the whole fabric has increased in the ratio of nearly three to one. On the other hand, it will appear, that four threads or cylinders being thus put together in one solid mass, might be supposed only one thread, or like the strands of a rope before it is twisted; but, to remedy this, the thread being shifted every time, the whole forms a body in which much aggregate matter is compressed, but where being less firmly united, the accession of strength acquired by the accumulation of materials, is partially counteracted by the want of equal firmness of junction.

Plate CXCIII. Fig. 4.

The second quality of the tweeled fabric, *susceptibility of receiving ornament*, arises from its capability of being inverted at pleasure, as in Fig. 9, Plate CXCIII. In this figure, we have as before four threads, and one alternately intersected; but here the 4 threads marked 1 and 2, are under the woof, while those marked 3 and 4 are above. As this in no way affects the solidity or strength of the texture, but is merely an auxiliary aid for the addition of ornament, the further discussion of

Plate CXCIII. Fig. 9.

this property will be more appropriately introduced in that part of this article which relates to the ornamental principles of texture.

Plate CXCIII. Fig. 8.

Plate CXCIII. Fig. 8, represents that kind of tweeled work which produces an ornamental effect, and adds even to the strength of a fabric, in so far as accumulation of matter can be considered in that light. The Figure represents a piece of velvet cut in section, and of that kind which, being woven upon a tweeled ground, is known by the name of Genoa velvet; a pretty strong presumption, that the origin of this manufacture at least in Europe is Italian.

That part, however, which produces the ornament, cannot properly be deemed likely to add much to the strength of the fabric, in so far as this is affected by any attempt at divulsion; but where the impulse is by friction, it must contribute very materially to its preservation. Hence, in practical use, velvets of every kind are in great estimation for three very substantial reasons.

1st, Because, by combining a great quantity of material in a small compass, they afford great warmth.

2d, From the great resistance which they oppose to external friction, they are very durable. And,

3d, Because, from the very nature of the texture, they afford the finest means of rich ornamental decoration.

The use of velvet cloths in cold weather, is a sufficient proof of the truth of the first. The manufacture of plush, corduroy, and other stuffs, for the dress of those exposed to the accidents of laborious employment, evinces the second; and the ornamented velvets and Wilton carpeting, are demonstrative of the third of these positions.

In the Figure, the diagonal form, which both the warp and woof of cloth assume, is very apparent from the smallness of the scale. Besides what this adds to the strength of the cloth, the flushed part, which appears interwoven at the darkly shaded intervals 1, 2, &c. forms, when finished, the whole covering, or upper surface. The principle, in so far as regards texture, is entirely the same as any other tweeled fabric, and the more particular discussion must be referred to the particular article.

Plate CXCIII. Fig. 10.

Plate CXCIII. Fig. 10, which represents corduroy, or king's cord, is merely striped velvet. The principle is entirely the same, and the figure itself will sufficiently evince, that the one is merely a copy of the other. The remaining Figures in the Plate, represent those kinds of work, which are of the most flimsy and open description of texture; those in which neither strength, warmth, or durability, are much required, and of which openness and transparency are the chief recommendations. For these reasons, the nature and principle of the texture may be better understood by considering them as mere superficies, than by any section which could be exhibited. The two kinds of gauze and catgut, which form the basis of all the varieties, are still exhibited in section; and the two others, which may be varied almost to infinity, are shown superficially.

Plate CXCIII. Fig. 11.

Plate CXCIII. Fig. 11, represents common gauze, or *linaw*, a substance very much used for various purposes. The essential difference between this description of cloth and all others, consists in the warp being twined or twisted like a rope during the operation of weaving, and hence it bears a considerable analogy to the substance usually known by the name of *lace*. The twining of gauze is not continued in the same direction, but is alternately from right to left, and *vice versa*, between every intersection of the woof. The fabric of gauze is always open, flimsy, and transparent, but, from the twining of the warp, it possesses an uncommon degree of strength and tenacity, in proportion to the quantity of materials which it contains. This quality, together with the transparency of the fabric, renders it peculiarly adapted for ornamental purposes of various kinds, particularly for flowering or figuring, either in the loom, or by the needle. In the warp of gauze, there arises a much greater degree of contraction during the weaving than in any other species of cloth, and this is produced by the twining. The geometrical ratio of this contraction must evidently depend entirely upon the same principle which regulates the contraction of the yarn in spinning, and therefore it is unnecessary to add to what has been already stated upon that subject. By inspecting the Figure, it will be apparent, that the twisting between every intersection of woof amounts precisely to one complete revolution of both threads; hence the following difference exists between this and every other species of weaving, namely, that the same thread of warp is always above the woof, and the contiguous thread is always below.

Plate CXCIII. Fig. 12.

Fig. 12, Plate CXCIII. represents a section of another species of twisted cloth, which is known by the name of catgut, and which differs only from the gauze, by being subjected to a greater degree of twine in weaving; for in place of one revolution between each intersection, a revolution and a half is always given, and thus the warp is alternately above and below, as in other kinds of weaving. The ratio of contraction in this, as in the former, is evidently reducible to the same principles which regulate the spinning.

Plate CXCIII. Fig. 13.

Fig. 13, Plate CXCIII. is a superficial representation of the most simple kind of ornamental net-work produced in the loom. It is called a whip-net by weavers, who use the term *whip* for any substance interwoven in cloth for ornamental purposes, when it is distinct from the ground of the fabric. In this, the difference is merely in the crossing of the warp, for it is very evident that the crossings at 1, 2, 3, 4, and 5, are of different threads from those at 6, 7, 8, and 9. The contraction in weaving this kind of stuff, is vastly greater than any other, and may very easily be ascertained with the utmost geometrical precision, depending entirely on the well understood principles of plane trigonometry; for it will hardly be necessary to take into the account what contraction takes place by the crossing of the threads in a fabric so very open and flimsy. Thus, if the diamond is crossed at 1 by a dotted line, four right angled triangles will be formed, and the contraction of the warp will be in the ratio, which the hypotheuse of each bears to the perpendicular; the former being the longitudinal measure of the warp when stretched in the loom, and the latter that of the cloth in its finished state. This reduces the contraction at once to the Pythagorean proposition, that the two are to each other in the ratio of their respective squares.

Plate CXCIII. Fig. 14.

Fig. 14, Plate CXCIII. represents, superficially, what is called the mail-net, and is merely a combination of common gauze and the whip net in the same fabric. The gauze here being in the same direction as the dotted line in the former Figure, the whole fabric is evidently a continued succession of right angled triangles, of which the woof forms the bases, the gauze part the perpendiculars, and the whip part the hypothenuses. The contraction here being very different, it is necessary that the gauze and whip parts should be stretched upon separate beams.

The above may be regarded rather as hints for the further investigation of the geometrical principles of the cloth manufacture, than as the absolute results of a perfect and matured theory. As nothing has been published upon the subject, the author of this article can only plead its obvious importance, as the motive which has led him to communicate what has occurred to him, as likely to promote a more ample and scientific enquiry.

Plate CXCIII Figs. 15, 16, 17.

We now proceed to state what occurs upon the ornamental principles of texture, referring the reader to Plate CXCIII., Fig. 15, 16, and, 17.

In order to produce ornamental figures upon cloths, it is necessary that the apparatus or mounting of the loom should be properly arranged for the purpose intended, previously to the commencement of the subsequent operations. The rules for this are pretty similar in all the different kinds of ornamental work, and the plans being previously drawn upon design paper, the first operation is to adapt the loom to the design. The designs, or patterns, are included between a certain number of parallel straight lines drawn upon the paper, and intersected by others drawn at right angles to the first. The lines which are drawn from the top to the bottom of the paper may be supposed to represent the warp, and those drawn across, the woof of the web; any number of threads being supposed to be included between every two lines. The paper thus forms a double scale, by which, in the first instance, the size and form of the pattern may be determined with great precision; and the whole subsequent operations of the weaver, both in mounting and working his loom, regulated with certainty and accuracy. To enable the projector of a new pattern to judge properly of its effects, when transferred from the paper to the cloth, it will be essentially necessary that he should bear constantly in his view the comparative scale of magnitude which the design will bear in each, regulating his ideas always by square or superficial measurement. Thus, in the large design, Fig. 16, Plate CXCIII. representing a bird perched upon the branch of a tree, it will be proper, in the *first* place, to count the number of spaces from the point of the bill to the extremity of the tail; and to render this the more easy, it is to be observed that every tenth line is drawn considerably bolder than the others. This number in the design is 135 spaces. Counting again from the stem of the branch, to the upper part of the bird's head, he will find 76 spaces. Between these spaces, therefore, the whole superficial measure of the pattern is contained. By the measure of the paper, this may be easily tried with a pair of compasses, and will be found to be nearly 6$\frac{1}{10}$ inches in length, by 3$\frac{6}{10}$ inches in breadth. Now, if this is to be woven in a reed containing 800 intervals in 37 inches, and if every interval contains five threads, supposed to be contained between every two parallel lines, the length will be 6.24 inches, and the breadth 3.52 inches nearly, so that the figure upon the cloth would be very nearly of the same dimensions as that upon the paper; but if a 1200 reed were used instead of an 800, the dimensions would be proportionally contracted.

Fig. 16.

A correct idea being formed of the design, the weaver may proceed to mount his loom according to the pattern, and this is done by two persons, one of whom takes from the design the instructions necessary for the other to follow in tying his cords. Previously to entering upon this, however, we shall shortly notice Figures 15, 16, and 17, of Plate CXCIII.

Fig. 15.

Fig. 15, Plate CXCIII, is a representation of the most simple species of table linen, which is merely an imitation of checker work of various sizes, and is known in Scotland, where the manufacture is chiefly practised, by the name of Dornock. When a pattern is formed upon tweeled cloth, by reversing the flushing as formerly explained, the two sides of the fabric being dissimilar, one may be supposed to be represented by the black marks, and the other by the part of the plate which is left uncoloured. For such a pattern as this, it is perfectly unnecessary to have recourse to the draw loom, for two sets of common tweel heddles moved in the ordinary way, by a double succession of heddles, are quite sufficient. The other part of Fig. 15, Plate CXCIII. is a design of that intermediate kind of ornamental work which is called diaper, and which partakes partly of the nature of the dornock, and partly of that of the damask and tapestry. The principle upon which all these species of goods are woven is entirely the same, and the only difference is in the extent of the design, and the means by which it is executed, which shall be explained in the subsequent part of this article, which treats of the construction of looms of various kinds. The last, Fig. 17, Plate CXCIII. is a design for a border of a handkerchief or napkin, which may be executed either in the manner of damask, or as the spotting is practised in the lighter fabrics.

Plate CXCIII. Fig. 15.

Fig. 17.

Construction of Looms.

Construction of looms.

The framing of looms is very differently constructed, and it is hardly possible to fix upon any precise or definite rule for practical adoption. The reciprocating motions which are necessary, and the constant recurrence of the percussion necessary to strike home the woof, require great firmness of resistance in the framing, as it is obviously the natural tendency of the reaction produced, to break the threads of warp. Strength, therefore, is not only a desirable, but an indispensible requisite in every machine for weaving cloth. There has been very little attention paid to ascertain, geometrically, the ratio of impulse produced by the operations of weaving, and nearly as little to calculate how the resistance may be most efficaciously and economically presented. In the construction of looms, like every thing else, the ideas of *mass* and *strength* have been confounded, and the loomwright seems most frequently to have supposed, that the usefulness of the utensil, when completed, was to be estimated by the quantity of wood which it contained. Some little attention, to avoid this useless and cumbrous expence, has been lately paid in the manufactories, where the business is conducted upon a large scale; but although these have been found equally efficacious, and much more economical than the former modes, they do not appear to have engaged proper attention, nor to have been scientifically calculated. In the way in which the manufacture of most kinds of cloth is conducted, the loom is very seldom the property of the manufacturer whose goods are woven in it. In general, a loom either belongs to the person who weaves with it, or to some other operative weaver, who lets it at a weekly rent. It is therefore not surprising, that the saving of a few shillings upon a loom, which, if well used, may last for perhaps fifty years or more, will be considered as a matter of very inferior importance to any individual; but were the aggregate of looms employed in the manufacture of cloth in Great Britain and Ireland estimated, the saving which might be effected by proper attention to the principles of their construction, without the smallest prejudice to their utility, would appear an object of great magnitude, even to the national economist.

Plates CXCIV. and CXCV.

Of the looms in use, we shall give a very brief account, referring to Pates CXCIV. and CXCV.

The common weaving loom for plain fabrics is represented in Plate CXCIV. Figs. 3. and 4. It consists of

Common weaving loom.

Plate CXCIV. Fig. 3.

Fig. 3. No. 2.

Fig. 3.

Heddles.

Fig. 4.

The lay.

Plate CXCIV. Fig. 6.

four upright posts, generally about 6 feet in height, and 4 inches by 3 in measure. The sides are made separately, and the two are connected by cross horizontal rails, which may be easily unfixed for the conveniency of removal. Fig. 3. is a horizontal section of the loom, the upper part being taken away, and shews a web as it appears while weaving: A, represents the beam or roller upon which the warp is wound before weaving; B, the lever by which the warp is kept at a proper degree of tension, and which will appear more plainly by referring to Fig. 3. No. 2. which is an elevation. The cord by which it is tightened or slackened, is there represented; and this may be done, almost instantaneously, by shifting the piece of wood C downwards to slacken, or upwards to tighten the warp. This part of the apparatus is only used in dense heavy fabrics, where great tension of the warp is necessary. In the tighter, a weight is used with a cord wound round the beam, which, besides keeping the warp always equally stretched, allows it to yield gently when the woof is struck home. C is the cloth beam or roller for receiving what has been compleated, and presenting a fresh surface to the weaver. In this Figure it is placed below, and receives the cloth after passing over D, which is called the breast beam. In looms for light fabrics, the cloth beam is placed where the breast beam D is represented, and D is entirely omitted. At C is a ratchet wheel, with a catch to resist the force at B, by which the warp is tightened. The yarn of the warp is kept clear by three rods, which pass through it at E. The crossing, by which every thread is kept distinct from all the others, is justly esteemed a point of the first consequence by the weaver, as the entire regularity of his warp depends upon his attention to the accuracy with which he preserves this. At F are the *heddles* or *healds* for raising and sinking the warp to receive the shuttle. In coarse fabrics they consist of two leaves, which rise and sink alternately in plain weaving, and in fine webs four are used. In fanciful weaving they are increased to an immense number, if the pattern be extensive. The lay which contains the reed, and by which the woof is struck home, is represented at G. In Fig. 4. which is a transverse elevation, showing the loom as it appears to a person standing immediately behind the weaver as he is seated at work; the same letters denote the same parts as in Fig. 3. The additional parts which are concealed in Fig. 3. are distinguished by the remaining letters. HH are levers, called jacks, by which the heddles are suspended from a cross rail upon the top of the loom; I is the cover or upper shell of the lay with the reed in it; K represents the cloth as it passes over the breast beam, previously to its being wound upon C, which appears below; at L are two pieces of wood, which are suspended from the heddles. Their use is to connect the heddles with the heddles below; for were the cord taken from the lower shaft of the heddles directly to the heddles, the whole pressure being upon the centre of the shaft, it must either be very strong, or it would yield in the middle. These are called spring staves. The two levers below at M are called marches, and are very useful, especially in ornamental weaving. The heddles appear below at N. By these the warp is opened to receive the shuttle and woof; and these are the principal agents in every kind of ornamental weaving, until they are superseded by the more extensive and complicated apparatus of the draw loom. In the two Figures described, it has been found impossible to give such a representation of the lay or instrument, which acts upon the woof, as would convey an adequate idea of its construction, because in both it was partially concealed by other parts of the loom. This defect is therefore supplied by Fig. 6. which, besides shewing the complete form, gives also an illustration of the manner of acquiring the agency of the fly or flying shuttle, now almost universally adopted in the cotton manufacture; and also one of the ways by which a number of different shuttles may be employed, both for the insertion of woof different in fineness, and also for that different in colour. In this Figure, A represents the cross spar of wood upon which the lay vibrates upon iron gudgeons or centres driven into each extremity, and resting upon the upper rails of the loom which are shewn in section. The suspending parts, which are called the swords, are represented at BB. The underpart of the lay, which is concealed in all the other Figures, appears at C. The boxes for the fly shuttle are visible at D. At E are two pieces of wood, called drivers, which slide upon smoothly polished iron spindles, and which give motion to the shuttle, of which there are two kinds, first, the common shuttle, wrought by the weaver's hand; and the second, the fly shuttle, upon which the drivers act. The drivers are drawn forward by the jerk of the weaver's hand, and the *impetus* must be so suddenly given, as to communicate such a degree of velocity as will lodge the shuttle in the opposite box, before the impelling force is counteracted by the friction of the shuttle on the board which supports it, and its own weight.

As diversity of woof renders a diversity of shuttles necessary, it becomes expedient to shift them rapidly, so that the operation may not be unnecessarily impeded. Many plans have been adopted for this purpose. That represented is perhaps as simple as any, and answers the purpose very well. The three boxes are constructed so as to slide easily up and down in a vertical direction. They are suspended by a cord or wire from the cross levers GG, which move upon centres in the swords or suspensary parts of the lay.

The pin H, being fixed so as to slide freely from right to left on the upper shell of the lay, the levers may be moved at pleasure by the mere shift of the weaver's hand, which works the lay. The driver, if drawn forward, would prevent an obstruction to the shifting of the boxes, but this may be very easily obviated by fixing two small pieces of whalebone, to act as springs, at I. From the ends of those springs, a cord may be carried to the driver, over a small pulley, to draw it back. This part of the machinery should never be used unless where it is indispensible; for the action of the springs, however slight, greatly increases the fatigue of the weaver.

Plate CXCIV. Fig. 5.

When it becomes necessary to employ many leaves of heddles for diversified patterns, the alternate levers, used in plain weaving for shifting the leaves, are no longer fit for the purpose, and the apparatus represented in Plate CXCIV. Fig. 5. becomes necessary. This apparatus, in narrow and light fabrics of cloth, may be constructed with one half of the trouble and expense necessary for broad and heavy work. The most extensive construction has been given for the use of those who find it necessary, and the lighter may be found by merely bisecting the figure vertically, and taking the left hand part. In this case, the heddles must be moved to the middle of the new figure. Instead of the jacks in the former figure, the levers at A are here used, one of which suspends every leaf of the heddles. From the extremities of these levers, a connection is formed, by means of a cord, with the marches at B, of which there are two sets, diverging from the centre of the loom to either extremity. In order that every treddle may operate equally on both sides, the spring-staves CC are used, and from these the connection is formed with the treddles. When a heddle is depressed, this part of the apparatus will raise the leaf or leaves with which it is connected, and by direct communication from the heddles, the sinking is produced.

Such an apparatus as this will form the most comprehensive range of pattern which can be produced, excepting by the draw-loom, which is used when the range of design exceeds what could be produced by leaves and treddles.

Plate CXXX.
Plate CXCIV.

But as the whole machinery of the draw-loom will be found in Plate CXXX. we shall proceed to describe the remaining Figures in Plate CXCIV. to which we have already referred.

Warping mill.

Plate CXCIV. Fig. 1. & 2.

The Figures 1. and 2. represent the construction of a warping mill, which takes the yarn from the bobbin, and disposes it in that form which is proper to constitute the warp of a web. Fig. 1. is a horizontal plan, and Fig. 2. an elevation of this useful and simple machine. From the centre of the mill, the spokes diverge like the radii of a circle to the circumference, as represented at A; and these spokes, being equidistant, serve to measure the warp with great accuracy, and of course ascertain the length of a web. In the Figure, the spokes being supposed to be 11¼ inches asunder, the whole perimeter, or measure of the mill, which contains 16 spokes, is 180 inches, or 4 English ells, of 45 inches each. The mill revolves upon its axis, and may be turned either way, by a rope or band moved by the trundle B, which is turned by the warper's hand. At E is a frame to contain the bobbins, which pass through what is termed the heck, and represented at D. In this heck are a number of finely polished and hard tempered steel pins, each containing a small hole at the upper part, to receive and guide one thread. The heck contains two parts, either of which may be lifted by a small handle below, and the eyes of each are alternately placed. Thus, when one is raised, a vacancy is formed between the threads, and when the other is raised, the vacancy is reversed. By this, the lease is formed at each end of the warp, and this is preserved by the pegs at F and G. These being carefully tied up, give the rule for the weaver to insert his rods. The warping mill is turned each way successively, until a sufficient number of threads are accumulated to form the breadth wanted. The chief part of a warper's duty is to be careful that every thread which may be broken be immediately tied, otherwise deficiences in the warp would occur, highly detrimental, and productive of very great loss of time to the weaver. The box which contains the heck, slides upon an upright post, and winds the warp round the mill in a spiral form, as will be seen in Fig. 2.

Of the common wheel, which is used for winding the yarn upon the bobbins, it has not been deemed necessary to give any figure, because it is very simple, and almost universally known. In the extended state of the cotton manufacture, it appeared, however, desirable, that some more speedy plan should be found than that, whereby a woman's whole time was occupied in winding a single thread upon a bobbin. The first of these machines was therefore constructed about the year 1790; and the writer of this article, who was then very young, had an opportunity of examining its principles, as it was first tried in the works where he received his earliest instructions in that branch of manufacture on which he now writes. Like most other new inventions, it was clumsily constructed, and defective in some material respects. This circumstance, together with that antipathy to improvement of every kind which is the peculiar characteristic of ignorance and obstinacy, created such a prejudice against the machine, that it was thrown aside as a piece of useless lumber. Another machine, different in principle, and constructed at Manchester, was then tried, and abandoned like the former, with the general and conclusive remark, *that they would not do.*

In this state they lay for some years, when a good practical mechanic accidentally discovered them. By a careful examination of that first noticed, he was convinced that the machine might be rendered valuable by a little care, and some slight improvements, which he accordingly executed, and produced a machine in every respect fit for its purpose. They were very soon copied, and the machine is now in general use, with a great saving to those who employ it. Different plans have since that time been devised, one of which is given in Figs. 7. and 8. of Plate CXCIV. the first being the profile, and the second the front of the machine. It consists of two sides, each containing a number of spindles, upon which the bobbins are placed, and the greater part of the moving machinery being in the centre, 50, 60, 80, or 100 bobbins may be driven at the same time, and the whole may easily be attended by two girls, one being stationed at each side.

Plate CXCIV. Fig. 7. & 8.

The large wheel, which puts all the rest in motion, appears at A, and from this first power, two distinct motions are derived. The first of these has for its object the production of the rotatory motion of the bobbin, in which respect the machine is in its principle very similar to those used for the purpose of spinning. The second is merely useful to direct the threads, so that every bobbin of both sets may be regularly and equally filled. The first of these motions is given by a band passing round the rim of the large wheel A, and communicating the motion to a pulley on the axis of the cylinder M, which is formed of hollow plates of tinned iron. From M, every spindle is driven by a small band, working the small pulley or screw on each; or every band, by passing over two screws, may drive two contiguous bobbins. The second motion, which guides the threads, takes its rise from a worm or endless screw B, on the axis of the large wheel A. The worm B turns the wheel C, on the upper end of a vertical shaft; on the bottom of which, a second worm, D, acts upon a wheel fixed upon the axis of a traverse wheel, formed like a heart, upon a principle which will afterwards be fully described, for producing either uniform, accelerated, or retarded motion. If the motion is made uniform, the bobbin will be built in the cylindrical form; but if is is accelerated at each extremity, and retarded in the centre, it will accumulate more yarn in the middle; and the bobbin, when filled, will appear shaped like a barrel. The traverse acts upon a lever, which presses against it at F; and this lever, being fixed to the guides HH, moving upon a common centre, one side is elevated while the other is depressed, and thus every part of the bobbins on both sides are equally or proportionally filled. At I, I, are two cops placed upon skewers, and the guides for the yarn will be seen above. The bobbins are at K, and the thin boards which cover the cylinder and banding appear at L. One of these machines, when properly driven, and carefully attended, will produce as much work as 20 or 30 women can do, if the cops are well built, so as to unwind easily, and without frequent breaking.

Plate CXXX.

In Plate CXXX. will be found three different kinds

Plate CXXX. Fig. 4.

of drawlooms, which are all that are used in Britain, excepting that occasionally employed in the manufacture of fanciful muslins, and the lighter fabrics of silk, which vary so little from the contruction of the damask draw loom, represented by Fig. 4, Plate CXCIII. that a person who is conversant with its construction might almost acquire such a knowledge of the other, even by a single inspection, as would be sufficient to ascertain the difference of their construction, and become entirely competent both to construct and apply it to practice. The draw-loom is used, where the threads of the warp must be raised in such prodigious variety of forms, that no machinery acted upon by distinct levers of any construction could be compressed within the limits of space which it would be possible to allot for their reception. The whole, therefore, consists of a prodigious assemblage of cordage, of which, by a judicious means of affording rapid selection, every individual part may be almost instantaneously set in motion, without confusion or danger of error. Some idea will be found of its construction, by examining the Plate, and by the following brief explanation.

The evident intention of the draw-loom is to combine the means of a very great variety of motion in a very small compass, and therefore that succession of looped threads or twines, which are called heddles or healds in other kinds of weaving, are, in this kind, all separate, and totally independent of each other. Their relative position and contiguity to each other is preserved by a horizontal platform, through which they pass, and which is sometimes a flat board, with a number of perforations placed like the divisions of a diagonal scale; and more frequently a frame of wood, with wires crossed over each other, the intervals between which answer the same purpose. This board or frame is represented at CC. Above this board are placed one, two, or three frames, each containing a number of small pullies. They are represented at B, and their position is that of inclined planes, forming angles of 45° with the horizon, and parallel to each other. All the twines, which compose the harness, pass over these pullies; and the farther extremity of each is fastened to another strong piece of wood, which is represented at E. The other extremity of each twine contains an eye for the warp to pass through, which, for the sake of smoothness and durability, is made of iron, copper, and sometimes glass. Under this is hung a weight to preserve the tension of the line, as represented at D. At a convenient distance between the pulley frame, and the farther extremity or table, another cord or *simple* is attached to each of those composing the horizontal part or tail of the harness, and these descend perpendicularly, and at right angles to the former towards the floor. They are represented at K, the middle set being tight, and in the proper position for working; the other sets slack and laid aside until it becomes necessary for an alteration of pattern to bring them into use, when they are substituted in their turns, and the set which they succeed laid aside. When, in the slack state, they are secured by a clasp of wood to preserve their regularity, and prevent accidents. Parallel to the simples at I is a strong cord with a number of rings upon it, to which smaller cords are tied, which communicate with the simples, and are called *lashes*. Every set of these lashes being selected in rotation, by the connecting cords between each set, they are pulled tight when their action upon the harness is required. The simple, thus pulled, deviates from the straight line, and is consequently contracted in the direct line of distance between its extremities; but every part of the whole apparatus being fast, excepting the lower part of the harness, where the weight is suspended, that part, yielding to the power exerted, rises, whilst the others, upon which no power is exerted, remain stationary, and thus an interval for the shuttle is formed in the warp. The design paper, giving an exact rule for the cording of the lashes, every part is thus raised with regularity and dispatch by the person employed, and the weaver has only to work his heddles as in ordinary weaving.

Plate CXXX. Fig. 4.

Plate CXXX. Fig. 1.

Fig. 1. of Plate CXXX. represents the carpet draw-loom, which, in principle, is entirely similar to the damask, the variations being merely such as to accommodate it to the particular kind of work for which it is designed with greater practical conveniency. The carpet fabric being composed of much coarser stuff than the damask, and containing a much smaller number of threads, there is little difficulty of combining all the changes necessary, without requiring that compression of apparatus indispensible in the damask. The harness and tail part at A, B, C and D are therefore on the same principle. The tail is made fast at E, as before; but the changes being comparatively few, the lashes are tied at once to the tail, and, descend through apertures in the horizontal board F. Each of them has a small wooden handle, like that commonly suspended by an ordinary bell rope, and these being placed in pairs, to correspond with the double fabric of cloth which composes the carpet, they are successively pulled, without any other trouble in selection than that which arises from taking them in regular succession. In the supplementary Figs. 2. and 3. the appearance of the pulley frame is exhibited more distinctly than in either of the other figures. Fig. 2. represents an elevated profile of the working part of the draw-loom, taken from the side remote from that where the harness is wrought; A being the frame work, B the pulley frame, C the perforated board or harness frame, and D the suspended weights. Fig. 3. is a profile elevation of the opposite side; B being, as before, the pulley frame, F the descending lashes, and G the handles or *bobs* by which they are successively pulled. See Carpet.

Fig. 2.

Fig. 3.

The last species of draw loom which we shall notice, is that which is called the patent draw-loom, although whether there is really any actual patent for it in existence or not we have been unable to ascertain. Its object which, however, is very imperfectly attained, is the reduction of labour, by saving that of the child, who is employed to draw the harness, and enabling the weaver, with little loss of time, to effect this operation for himself, independently of the aid of another person. In this respect, its claim to the possession of exclusive privilege seems very questionable were it disputed; for it is a very simple and obvious extension of the principle of the common diaper harness loom, which has been known and used for very many years, and, like the common draw-loom, is an invention which did not originate in Britain, nor probably even in Europe. The harness part of the patent draw-loom, instead of passing through a frame or frames of pullies, has its tail attached perpendicularly to the roof of the shop, immediately above the harness. The simples are brought from it in a horizontal direction, and their extremities fastened above the weaver's head, but at some distance behind. The lashes, therefore, descend perpendicularly, and are kept in regular order upon a cord. When they are tightened, the tail of the harness is therefore brought forward, and each cord of the tail has a knot tied upon it. An instrument called a comb, from its resemblance to one, is also suspended horizontally upon centres, and moves upon a fulcrum like a lever, the teeth of the comb being at a very small distance before the knots on the tail, and inclined upwards in a curve like the teeth of a rake. When the simples are tightened, which the weaver does with his left hand, those cords of the tail to which they are attached are pulled forward, and lodged between the teeth of the comb. The other extremity of the lever being then pulled down, the teeth rise, and by taking hold of the knots, lift all those cords in the tail which are between the teeth. The lower end of the comb lever is secured by a knot on the cord slipping into a notch, and secured there until it becomes necessary to relieve those cords, and pull up a fresh set, which is done by lowering the comb, and proceeding as before. The comb is the only point in which this apparatus deviates in the least from the old diaper mounting.

From the strength of the stuff, whether linen or woollen, of which damasks and carpets are woven, this seems to open an admirable and extensive field for the application of weaving by power. The writer of this article has turned his attention much to the subject, and is confident that the object in view could be very easily effected by an apparatus somewhat similar in principle to what he has successfully employed in another branch of the manufacture, and which he is only prevented from detailing by the length to which this extensive article has unavoidably led him. For the woollen, which requires no dressing, and is strong and heavy in the fabric, it is peculiarly adapted. The reference letters are as follow: (This Figure is given at the bottom of one of the Plates of CROSS TEXTURE.) A, distinguishes the upper rail or cape of the loom, which is shewn in profile; B is the roller or beam upon which the warp C is stretched; D is the perforated board or frame which regulates the cords of the harness; E is the front mounting or heddles, which the weaver works by his feet, and the eyes of which, being somewhat longer than the whole aperture of the warp which receives the shuttle, raises a part of what is above, by the harness, and sinks a part of what is below, thus forming the reversed flushing upon the upper and under parts of the fabric, as will appear by the crossings of the warp threads, and which arrangement is common to every species of harness work, of whatever description; F is the lever which contains the comb, and which is operated upon by the cord and handle G. The beam which receives the cloth when the operation is completed, is represented at H. All the varieties of fanciful weaving are founded upon principles similar to the above. The mode and apparatus necessary for opening the warp may be varied to infinity, and it would be impossible to enter into the detail necessary for every individual part. This exposition of some of the most complicated operations, however, includes most of the general principles upon which the construction of looms depends.

Construction of power looms. PLATE CXCV.

The last subject connected with the construction of looms which we can introduce, is the application of mechanical power to the operations of weaving, which is still in an infant and imperfect state. Such elucidation as we can give of this part of the subject, will be more perspicuous, both to the common and professional reader, by referring him to Plate CXCV.

Wiper loom. PLATE CXCV. Fig. 1.

In this Plate, Fig. 1. represents the profile elevation of that kind of power loom, which was first used in Scotland at the Milntown printfield in Dumbartonshire, and which was introduced by the late Mr Robert Miller, who took a patent for its use, which, we believe, is not yet expired, although looms of this description, whether strictly within the range of the patent or not we do not pretend to ascertain, have been used in various parts of the country. The motions of this, and all power looms, may be reduced to three, viz.

1st, That which, by operating on the heddles, opens the warp to receive the shuttle which inserts the woof.

2d, That which generates the oscillatory motion of the lay and reed, for striking home the woof after insertion, to form the texture.

3d, The alternate motion by which the woof is inserted, by successively driving the shuttle from one side of the web to the other, whilst the warp remains open.

Besides these three principal motions, a fourth is used, by which the cloth is gradually wound upon the receiving beam, and fresh warp presented, without impeding the progress of the other operations of the loom.

The whole of these operations take their primary impetus from the revolution of an iron horizontal shaft, which extends across the loom, and one end of which appears at A. The impetus for the different motions is taken by either four or six treddles; a horizontal plan of 4 is given in Figure 5. If six are required, they may be added, one being placed on either side of those represented in the Figure. Of the four represented, the motion of the heddles is effected by that in the centre numbered 1, and those of the lay by 2. Those of the shuttle are given by 3 and 4. The whole motions are given by eccentric wheels called wipers, of the geometrical construction of which, as they are applicable to an immense and boundless variety of machinery, we shall take the present opportunity to give a cursory account, referring to Figure 6.

PLATE CXCV. Fig. 5.

Fig. 6.

The mechanical operation of the traverse, or wiper, depends entirely upon the divergence or convergence of the various parts of the rim to or from the centre of motion, and hence it may be assimilated to the mechanical power and effect of the inclined plane, being merely an inclined plane applied to a circle. As in its formation the inclination of the plane may be infinitely varied, it becomes capable of producing every variety of uniform accelerated or retarded motion, and by judicious combination, not only the ratio, but the direction of the motion, may be infinitely varied. It is only with the first of these properties that we have in this article any connection; for in the operations of weaving, uniformity of motion, in as far as it is competent to the purpose, is peculiarly desirable, from the circumstance of its operating with the least possible stress upon the warp, a matter of the first and most indispensible importance. For the construction of an equable and uniform traverse, the following simple practical instructions seem all that are necessary, to render it applicable to weaving by power. Let the circle *a b* be constructed of any convenient dimensions, but the larger the better where there is sufficient room to contain it in its working position, and from the centre draw a great number of radii at equal distances through the circumference, and produce them to the length required. On the outer part of the circle set off a distance on the produced line *c d*, equal to the whole range which the revolution of the wheel on its centre is required to produce upon any body acting by pressure against it. The two diameters at right angles to each other will then be similar to the transverse and conjugate axes of an ellipse. The whole range of motion being thus expressed by the excess of the outer above the inner circle, the whole may be divided either into equal parts for uniform motion, or into such geometrical proportions, as will effect the acceleration or retardation re-

Construction of the traverse, or wiper.

quired. In the Figure, the motion required being uniform, the divisions are equal. The divisions on the radii being joined by oblique lines, the wheel will be completed, and the more numerous the radii are, the nearer will be the approximation to geometrical accuracy. Thus, in the Figure, the whole range of motion is the excess of the line from the centre to *c*, above that from the centre to *b*, and, this being equally divided, the motion must be uniform. Upon this principle, depends the construction of all traverse wheels for the production of motion. The traverse, therefore, at A, being constructed on this principle, it is only necessary further to observe, that if it is made in two separate pieces, one of which would move the treddle 1, and the other the treddle 2, the warp will be regularly and alternately opened by the successive action of these two parts; or if the centre of motion, where the warp is closed, be made at 2, both openings or sheds would be formed by half a revolution of the shaft, and only one treddle would be necessary, for the other would form itself simply, by suspending a weight from the heddle. In the latter case, it would be better to form the range upon the semicircle than the quadrant, which may easily be done.

Fig. 1.

The second necessary motion is that of the lay, which is done by a wheel similar to the former. If the traverse for the heddles operates twice in one revolution of the axis, that of the lay must reciprocate four times; but this is perfectly unnecessary in either. Suppose the traverse at A, Fig. 1, to operate successively on two alternate treddles for the fast motion, and twice on the same treddle for the second, then the effect required will be produced, and this is the usual way. In this plan of power looms, the lay is only brought back by the traverse, and returns by the operation of a weight at D. The shuttle motion may be given, by attaching the driver cords to two treddles, struck alternately by wipers fixed on the axis; or it may be communicated as in the crank loom, Fig. 2, which we shall now describe.

Crank loom.
Plate CXCV.
Fig. 2.

Fig. 7.

Fig. 8.

The crank loom is set in motion by the operation of two transverse shafts, and operates entirely without treddles of any kind. The first shaft, the end of which appears at A, is placed perpendicularly under the heddles, and gives motion to them by a double or alternate crank, the Figure of which is shown by Figure 7. As one revolution of this shaft consequently opens the heddles twice, it is necessary that the lay should operate twice in the same space of time. This, therefore, is effected by a separate shaft with two direct cranks, and which revolves twice in the same space of time that the former undergoes one revolution. The particular forms of the crank, and the wheels which connect them, are so clearly pointed out in the Figure, that it seems unnecessary to go further into detail in the description of this machine, than to explain the other Figure 8, which operates on the cords which gave motion to the shuttle. This double or reciprocating lever is fixed to vibrate upon its centre under the web, and rather in front of the heddles. The cross shafts of the lever at A and B, are alternately struck by projecting pieces of iron fixed on the front shaft, and thus the motion is given alternately, according to the end of the lever which is struck. This may be equally well applied, and frequently is so, to the wiper loom, Fig. 1; for both the time and quantum of motion in each machine is precisely the same.

A third kind of power loom, invented by Mr Johnson, was introduced some time ago by Mr Shirreff of Glasgow, which, from its form, is called the vertical loom, and which possesses, in point of utility and convenience, some essential advantages over either of the above.

This loom is represented in Plates CXCVI. and CXCVII., and its construction will be understood from the following description.

Johnson's vertical loom
Plates CXCVI. and CXCVII.

The vertical position of the web requires that the slaise, or lay, (*i. e.* the frame which carries the reed and shuttle boxes,) should have a vertical reciprocating motion, and it accordingly strikes the reed upwards against the cloth in drawing up the woof. The yarn beam is placed below, and the yarn passes from it first up through the heddles, or harness, and then through the reed. It passes thence to the temples, and upwards to a roller, which serves to direct its motion a little backwards to the cloth-beam, upon which it is wound up by the machine, in proportion as the cloth is formed.

It is obvious, that the healds must act in this loom horizontally, which is done in a very simple manner, whilst the pecking motion (*i. e.* the motion of the shuttle) is produced by means of a very natural contrivance, imitating with great precision the motion of the weaver when working with his fly shuttle. In case any thing occurs to interrupt the motion of the shuttle, that very interruption causes the loom to stop, and prevents all further harm to the yarn.

From this general description of the loom, it is hoped that, by the help of a short reference, the Figures will easily convey a distinct notion of its general construction.

Plate CXCVI.

Plate CXCVI. is a profile elevation of a cast-iron frame containing two of the vertical looms.

Plate CXCVII.

Plate CXCVII. is a front elevation of one of the looms.

The same letter refers to the same part, when they occur, in both Figures.

The pully A A receives its motion by a belt from the mill work, and it moves the loom when a bayonet B connects it with the first axle C *c*.

On the axle C *c* are two cranks, by means of which there is a vertical reciprocating motion communicated to the slaise DEFG, Plate CXCVII.

HI is the reed, and DH, DE, the shuttle boxes.

The slaise is guided in its vertical reciprocating motion by the side posts of the framing, and strikes the reed upwards against the cloth in driving up the woof.

By means of the wheels K, L, motion is communicated from the first axle C *c* to the second axle M *m*, which, by cranks and other contrivances, produces a horizontal motion in the healds NO, and it does this at the same time that it produces the pecking motion, (*i. e.* the motion which drives the shuttle,) by means of the alternate motion of the small vertical axle PR, and its projecting arm QR, which arm gives motion to a fly shuttle by thongs, &c.

ST is the yarn-beam, from which the warp passes upwards through the reed, and the cloth, guided by a roller, passes backwards, and is wound up in proportion as it is formed upon the cloth-beam V W. This is done by means of a ratchet wheeel X worked by the motion of the slaise, but so contrived as not to take off the cloth unless it be sufficiently thick.

Z, a small balance-wheel for regulating the motion.

Duncan's new vibrating loom.

The following is a description of a loom invented by the author of this article, with a view to remedy some of the inconveniences which appeared to him to attach most strongly to the vertical looms of the preceding construction, which he had examined. A model was constructed under his inspection, sufficient to weave a narrow muslin web, which was tried as an experiment, and the pressure of attention attending another important mechanical operation in which he was then engaged, prevented him from bestowing upon it all the attention which might have

Plate CXCV. Figs. 3, 4.

been desirable, previous to its introduction to extensive practice. The experiments made were sufficient to convince him of the efficiency of its construction, and he has no doubt of its practical utility if cautiously and prudently tried, and improved where it might be found practically defective. Its chief recommendations are its extreme simplicity of construction, and its capability of working with very little friction, and consequently both requiring little power to move it, and operating with proportionally little of the stress produced by reaction on the yarn. Fig. 3, is a front, and Fig. 4, a profile elevation of this machine.

The machine consists of two wooden frames, one of which is supported by four posts, and may be made about 30 inches high. The dimensions, in length and breadth, may be similar to those of a common loom. The under frame is distinguished by AB in both Figures. The upper frame is rectangular, and is about six inches shorter than the under one, and has no posts. In the middle of the under frame are two screws, by which the upper frame is supported in centres, and on which it vibrates, so that either side may be alternately elevated and depressed, and thus an inclined plane may be formed either to the right or left. By this inclination of the plane in which the web is placed, the shuttle will run from one side of the web to the other, merely by its own gravity, independent of any external impulse, and thus a very troublesome part of the machinery of a power loom may be totally saved. But as celerity of motion in the shuttle is peculiarly desirable, and as the motion produced by mere gravitation is very slow, where the inclination is small, the velocity of the shuttle may be easily increased to prodigious rapidity, by the addition of a very simple apparatus, which is added to the left side of the Figure 3, exactly the counterpart of this, being also requisite at the right The following short description of the construction of the *lay*, and apparatus connected with it, will render this, it is hoped, very perspicuous. In the original model, the lay was morticed into a cross frame of wood, and run upon four small brass wheels upon the frame; but as a pendulum was found of essential advantage to the regulation of the oscillation, the motion below, upon centres, is a material improvement, both in easiness of motion and regularity. At G is a stout bar of flat iron, firmly screwed to and depending from the centre of motion of the upper frame, so as to vibrate along with it, and to the end of this is appended a ball of lead or other ponderous metal. Across this is the short shaft H, upon which the lay vibrates at the joints I, I. The circular form of the swords of the lay renders them more conveniently adapted for the oscillation, as were the centre shaft *produced*, so as to render the whole lay square or rectangular, it must either be hung at an inconvenient height, or the floor must be hollowed out to admit of the oscillation. When the loom is set in motion, supposing the right side first to descend, the lay will be forced back towards the heddles by the cranked lever R coming in contact with the stop S, and this motion will be effected by the connecting rod T, which may be of strong wire. When the inclined plane is thus formed, the shuttle will descend upon it by its own gravity, and lodge in the opposite box. But if the motion is to be greatly accelerated, an upright lever E, moving on the centre F, may be used, and a spindle and driver added to the box at K, as in common looms. Then, if the short tail of the upright lever at K is suddenly checked, by coming in contact with any stop fixed to the frame work, the upper end of the lever E will be thrown forward, with a velocity proportional to the excess of the length of the upright part of the lever E above the short tail, and will project the driver, and consequently the shuttle, with very great rapidity. The shuttle may be retained in the box until acted upon by the lever, by the pressure of a slight spring in the inside of the box. When the left side of the loom is depressed, and the right side elevated, the lever will fall back by the simple change of its centre of gravity, produced by the oscillation, and the driver will follow by the impetus of the shuttle returning. The back part of the driver ought to be circular, to fit the arc formed by the motion of the impelling lever :—a similar apparatus may be added to the box on the other side. By these simple means all the motions of the lay are produced.

As the heddles do not retain their perpendicularity, but are affected by the vibration of the machine, it is proper that the upper and under shaft should be kept from swinging ; and this may be easily effected by a piece of wire passing through both, and secured by a nut between the shafts at either extremity. They are hung by a cord passing over a small pulley at the upper end of the standard U, which is fixed to the oscillating frame. The motion is given to the heddles by the lever V, which is connected to the front leaf by the joint W. The extremity of the lever requires merely to be fixed to the lower frame, so that it can neither rise nor sink, and this may be sufficiently done by two cords or leather belts. The opening of the warp may be made more or less as these cords approach to, or recede from the centre V. By this simple apparatus the alternate motion of the heddles is produced, for the back leaf requires only a sufficient weight to overbalance the front, and keep the connecting cords which pass over the pullies at U tight, whether ascending or descending. The shifting apparatus for rolling the cloth on the receiving beam L, and unwinding the warp from the beam Y, is also extremely simple, and may be rendered very correct. On the end of the axis of the receiving or cloth beam at O, is an obliquely cut spur wheel, which is wrought by a worm or endless screw at P. Upon the short axis, which carries the worm, is also a small ratchet wheel, which, in this case, is supposed to contain only four divisions or teeth. When the right hand side of the loom is depressed by the vibration, one of the teeth of the ratchet, coming in contact with the upper end of the iron stop Q, which is screwed to the immoveable part of the frame work, moves the tooth one half of the range between that and the next ; and a similar stop may be so adjusted as to complete the motion, when the same side is carried to its greatest elevation. Thus eight crossings of the woof will be inserted by every revolution of the worm, and the number of teeth on the oblique wheel being made proportional to the quantity of woof required upon any determinate measure, as an inch or a yard, this may be obtained by shifting the oblique wheel, and substituting another whose teeth are proportional to the quantity sought. For this reason the wheel O ought not to be rivetted upon the axis, but fixed on an octagon or a square, and secured by a screw and nut, which may be easily removed.

Such is the general outline of the principles of this machine, which seems to possess the advantages of simplicity and easiness of working, in a degree considerably superior to any of the former ; but the oscillatory motion of the whole warp certainly exposes it, in a peculiar degree, to the action of the atmosphere, in so far as that may be injurious to the dressing. Until this part of the process of manufacture be more fully examined and further improved, both in its chemical and mechanical department, every attempt at weaving of cloth by the agency of mechanical power, will be liable to very great difficulty. Of what has been done, it may now be proper to give some account, referring for a general view of the mechanical apparatus to Figs. 9, 10, and 11. of Plate CXCV.

Plate CXCV. Figs. 9, 10, 11.

Machinery for Dressing Warps.

Machinery for dressing warps.

An essential point in every kind of weaving is, that the warp be properly prepared or dressed, and this varies according to the nature of the raw material.

In the woollen manufacture, it is only necessary to have the yarn well scoured, to free it from those impurities which may have been originally in the wool, or which it may have contracted in any of the preparatory processes of carding or spinning. For the purpose of scouring, urine is generally used. After going to the loom, the weaver has no occasion to use any further kind of dressing, and it is only incumbent on him to remove obstructions, such as knots, lumps, snarls, twists, &c. which might prevent the free passage of his warp through the heddles and reed, or which, should they pass, would intercept the woof, or injure the appearance of the fabric.

The silk, like the woollen, requires no dressing material to be employed. It is, however, sometimes considered to be useful for increasing the tenacity of weak stuff of this kind, to brush over it very lightly, and in small quantity, a very thin solution of any of the transparent vegetable gums. Gum arabic is most commonly employed for this purpose, which, however, is rarely necessary.

In flax or linen yarn, the dressing is perhaps the most important and difficult part of the whole duty of the weaver. The substance employed is a vegetable mucilage, generally prepared from flour and water, by the simple operation of boiling them together. It is therefore the same substance as that which bookbinders use for pasting together sheets of paper or pasteboard, excepting that the latter increase the cohesive power of the paste by the addition of a solution of alum, which is omitted by the weaver, probably because the substance would, in that case, require more time and labour in drying than he finds it convenient to bestow. The use of this substance in the weaver's operation, is evidently the same as in that of the bookbinder, namely, to promote cohesion. But when this is effected, he is still liable to a very serious inconveniency, which often impedes him much in the subsequent operation of weaving, and also frequently deteriorates the quality of his cloth, both in point of smoothness of surface and equality of fabric. This inconveniency arises from the effect of the oxygen, or vital part of the atmospherical air, acting too rapidly on the vegetable substance of which his mucilage or dressing is composed; and when this takes place to a great degree, the threads lose so much of their pliancy and elasticity, as proves very detrimental to the form which they must assume in the texture. No remedy has yet been devised for this, although the inconvenience is much a subject of complaint among weavers, especially those of linen or flaxen goods. In order to counteract, as far as he can, this impediment to his work, the shop where a weaver works is almost constantly upon the ground floor of the house, and he dispenses with fire as much as he possibly can, even in the coldest weather, and is only a little more profuse, when in consequence of excessive rains, the moisture, which is most rapidly absorbed by his warp, produces nearly as great an inconvenience as the heat, which he is in general so anxious to avoid. The only two antidotes which have hitherto been tried for these inconveniences are as follow: 1st, By mixing the salt brine or pickle of beef or herrings, in small quantities, with the dressing, in dry hot weather. This produces a beneficial effect to a certain degree; but should the weather change suddenly, the excessive tendency of the saline substance to imbibe moisture, frequently produces more trouble and delay to the weaver, than even the hardness produced by the heat itself. 2dly, By inducing a degree of fermentation in the dressing previously to using it. This is very frequently practised, and found very beneficial; but although it certainly has a considerable tendency to resist the atmosphere, it probably in some measure diminishes the cohesive quality.

It seems probable that this is the plan used in India in the decoction of rice, with which the Indian weavers dress their cotton yarns; and from the heat of the climate in that country, and the little pains they are known to take in order to preclude the action of the air, it is to be wished that we were better acquainted with the peculiar nature of their process. It is also common sometimes to use a little butter milk along with dressing; and this being an animal substance, we are inclined to think might, with a little pains to investigate the proper quantity and best process, be made of considerable use. It might also be proper to make some experiments with the different kinds of animal *glutina* which are most easily obtained. We know that in another part of the process of manufacturing cotton, namely, the dyeing of the colour known by the name of Turkey red, the whole preparatory process consists merely in impregnating the vegetable substance with animal matter. The colour is at length given very easily, merely by boiling the cotton previously prepared in a decoction of madder, which is itself a vegetable substance. The animal substances used are sheep's dung and bullock's blood. We know also that colour is destroyed by the action of oxygen very rapidly; we further know, that the very act of fermentation in a great degree deoxydates the substance upon which it acts. From all these circumstances we may infer, that any substance which will resist the oxygen most effectually, is the substance wanted. From this it appears probable, that some benefit might arise from trials of certain quantities of the weakest kinds of animal jellies; but as we are not aware that this has been attempted, it is hinted at with hesitation. The common weaver would probably be so disgusted with the labour and loss of time, which it would cost him to dry the first dressing with his fan, that these inconveniences would induce him to relinquish the experiment with disgust, as totally impracticable and nugatory. But when the immense importance of supplying this desideratum in a most extensive manufacture is considered, the man of science might find his time less usefully and profitably directed, than in such an investigation.

Whatever advantage might accrue to the manufacture of cloth by chemical improvement, would be of very essential importance in all the larger establishments, where regularity and economy are equally indispensible with proper apparatus. In short, taken in every view, this is the *grand desideratum* both in the linen and cotton manufactures.

We are only acquainted with three attempts to introduce the agency of mechanics for the purpose of dressing the whole warps of webs previous to commencing the operation of weaving; and it may be no injustice to the inventors to state, that we still consider even the mechanical apparatus obviously susceptible of very great improvement.

The first of these machines has been used both in England and in Scotland, in some manufactories, but has not come into general practice. It originated in a large work erected at Stockport in Cheshire; the second was introduced by Mr John Monteith at Pollockshaws; and the third by Mr James Dunlop at Barrowfield, near Glasgow.

Stockport Dressing Machine.

Stockport dressing machine. Plate CXCV. Fig. 9.

In Fig. 9. is a profile elevation of the principal working parts of this machine, which is introduced more because it is the first attempt of the kind, and as an illustration of the first approach to mechanical improvement, than for any real merit or utility which it possesses, as it is evidently both complicated and imperfect in many respects. The frame-work at AA consists of two similar parts, meeting in the centre, where the receiving beam E, which is afterwards to be carried to the loom, is placed. The yarn, in this process, is not warped upon a mill, but certain portions of it are wound from cops or bobbins, upon separate beams or cylinders, which are carried to the dressing machine, where they are placed horizontally at the extremities at CCC; and in this instance six of these (three at either side) are supposed to be combined, for the purpose of forming one warp. From the beams at C, the warp is carried over the two directing pullies at DD, and received on the roller E. The mucilage is placed in a trough placed under the beams, which, being entirely similar in principle to the plan in Fig. 10. is omitted in this part of the Plate. The brushing of the warp is effected by four brushes of a length sufficient to cover the whole breadth of the surface, two of which act above, and two below. They are marked BBBB, and receive their motion by means of a double lever GG, from a crank at F. The shaft is kept always parallel to the horizon, by its connection with the balance-levers on each side of E. The drying part of the operation is effected by the revolution of wooden fanners at H, previous to the warp being received on the beam at E. Before reaching the receiving-beam, the warp passes through a pair of *heddles*, or *healds*, to preserve the lease, and these are kept slack, that they may not break the warp in the passage. When a web is dressed, it is taken to the loom, and another set of heddles, containing the *thrum*, or remainder of a finished web, are substituted, and a new warp being twisted to the thrum, the operation proceeds. A great, and perhaps irreparable defect in this operation, is its immense friction; for, in order to preserve the regularity of the warp, it is divided by a succession of reeds, which is a clumsy and injurious expedient; for the dressing is much rubbed off, and the warp frequently broken by the friction of the reeds, especially when clotted by the mucilage.

Pollockshaws Dressing Machine.

Pollockshaws dressing machine. Plate CXCV. Fig. 10.

To improve this machine, that introduced at Pollockshaws by Mr Monteith was invented, and in some respects it is certainly very superior to the former. It will be seen in Fig. 10. This machine, like the former, consists of two parts, meeting in a common centre, where it is wound upon the beam, from which it is afterwards to be woven. The motion is taken from the moving power by the pulley A upon the same axis, with which is a small bevel-wheel, concealed behind the small circle near the centre. This operating by means of anothe bevel-wheel also concealed, turns the upright iron-spindle B, by which the four brushes are set in motion. The bevel-wheel at B operates upon that at C, and gives motion to two horizontal shafts extending longitudinally along the machine. Those at DD on each end move two cylinders covered as brushes, which operate upon the warp. The beam G contains the yarn previously to its being dressed, and the mucilage is supplied by its revolution in the trough, as represented in the Figure. Another roller may be beneficially placed above it, to rub off any redundant quantity, and return it into the trough. The drying part of the operation is effected by the revolution of the fanners EE upon their own axes; and this motion is taken from the wheel A, by bands passing over the directing-pullies at F. The motions given to the brushes, and those to the fanners, are so contrived, that either may proceed while the other is at rest, so that the warp may be neither too hastily nor too slowly dried. After passing over the directing-rollers at HH, the dressed warp is received below upon a beam concealed by the large wheel A. The warp in this machine is also kept regular by passing through reeds, which is a serious objection to it. In this machine, the brushing is effected in a much neater form than in the former; but the other objections being still unobviated, render it at least problematical, whether it may ultimately be found valuable, unless very much improved.

Barrowfield Dressing Machine.

Barrowfield dressing machine. Plate CXCV. Fig. 11.

The last attempt with which we are acquainted, is that made by Mr Dunlop, at Barrowfield, which combines part of the common operation, and does little more than supersede the labour of fanning by the hand. It is represented by Fig. 11. In this machine, the warp is taken from the beam at B, and received upon that at A after being dressed. Here nothing more than that division of labour, which keeps one man constantly employed in dressing the yarn which is to be woven by another, is attempted. Every part of the operation, viz. *clearing* the warp, *picking* and brushing it, is as much a manual operation as that done in the weaving loom. The warp is in the same way divided by rods, and these are brought down by clearing the warp with a comb, as in common weaving. The brushing being finished, the operator saves merely the labour of fanning, by setting the fanners below in motion by mechanical power, communicated by the band GG. The fanners at C are inclosed in a thin box D, and thus the current of air which in the other machines diverges in every direction, is entirely directed to one part of the warp, escaping through an aperture in the box, represented by the dotted line. This aperture is successively directed upon every part of the warp by the revolution of the traverse-wheel F, which acts by pressure upon the lever E, connected with the lower part of the box by a joint. The rotatory motion may be given to the traverse by the oblique shaft H, which will receive it from the axis of the fanners. The use of the box in this machine seems judiciously to confine the current of air to that line of direction where it is useful. The facility of picking the warp is also of importance; for no machine can ever be made to effect that by physical means, which is the result of the metaphysical operation of the mind. Were the means of brushing by power added, which might be easily done, the attendance of one man would be sufficient for all the picking generally required in three or four machines; and in this case the invention might be rendered as far useful as the defect in the chemical part will admit.

In this cursory detail of the principles of the cloth manufacture, and of the most prominent operations, much must unavoidably be left very imperfectly treated. It may be said as an apology, that, independently of the extent of the subject, and the difficulty of compressing it within any tolerable limits, in a work devoted to general science, sufficient instances have been adduced to evince, that, theoretically, the subject itself as never been properly studied; and that even many of the practical improvements appear to be still in a state of infancy, or at least very far from maturity. (J. D.)

CLOUD. See METEOROLOGY.

CLOVER. See AGRICULTURE *Index.*

CLOVIS. See FRANCE.

CLUNY, a small town of France, situated between two mountains on the Grone, in the department of the Saone and Loire, and is celebrated for its famous abbey, which is now in ruins. Its principal manufactures are woollen and silken stuffs; and it carries on a small commerce in wines, corn, and sheep skins. Population, 3814. (*w*)

CLUPEA. See ANCHOVY and ICHTHYOLOGY.

CLUSIA, a genus of plants of the class Polygamia, and order Monœcia. See BOTANY, p. 345.

CLUYTIA, a genus of plants of the class Diœcia, and order Gynandria. See BOTANY, p. 340.

CLYDE. See LANARKSHIRE and RENFREWSHIRE.

CLYPEOLA, a genus of plants of the class Tetradynamia, and order Siliculosa. See BOTANY, p. 260.

CNECRUM, a genus of plants of the class Triandria, and order Monogynia. See BOTANY, p. 97.

CNEPH. See EGYPT.

CNESTIS, a genus of plants of the class Decandria, and order Pentagynia. See BOTANY, p. 219.

CNICUS, a genus of plants of the class Syngenesia, and order Polygamia Æqualis. See BOTANY, p. 293.

COACH, a covered carriage, moveable on wheels, for the conveyance of passengers. A carriage of pleasure or state, distinguished from a chariot by having seats fronting each other; *Johnson.* Fr. *Coche.* Ita. *Cocchio.* Sp. *Côche.* Bel. *Koetswagen.* Teu. *Kobzen. Kutzsche á verbo Hungarico kotczy, idem, quod in Hungaria hoc curriculi genus primum inventum fuerit.* See *Ductor in Linguas,* by John Minshew.

For the numbers in different countries, the origin, and other particulars, see CARRIAGE.

COACH-BOX, the seat on which the person who drives the coach sits.

COACH, HACKNEY. See CARRIAGE. Hackney coaches are under the controul of the police. In order to prevent imposition, no hackney coachman is entitled to payment of his fare without producing, if required, a set of regulations, printed and issued under the authority of the police magistrate.

Hackney coaches pay duty to government, as other public carriages.

COACH, MAIL. These carriages are under the superintendance of the post office, and are employed chiefly for the purpose of conveying the mails all over the country. One contractor furnishes the whole, and is allowed a certain sum by the post-office for every mile each coach runs. They are also exempted at present from payment of toll duties, and are, alongst with other stage coaches, limited, by act of parliament, in the number of passengers they carry, the height they are to be made from the ground, and in many other particulars, intended for the greater security of travellers.

Mail coaches generally go at the rate ef seven miles an hour, including all stoppages.

COACH-MAKER, the artificer whose trade is to make coaches.

COACH-MAKING.

THE art or (technically) *calling* of coach-making, is the method of constructing and executing all the various parts necessary to, or connected with, any description of carriage used for the conveyance of passengers.

Without entering minutely into the detail of the manufacture of carriages, we shall state the general objects the coach-maker has in view in constructing them, the different branches into which the art is divided, mentioning the materials of which the various parts are composed, with any of the peculiarities in the execution of the work that may be worthy of remark.

As some confusion might arise from using the word carriage, meaning the whole vehicle complete, and *carriage,* as technically undestood by coach-makers, meaning the frame-work upon which the axle trees and springs are fixed, without including either the wheels or body of the machine, it is necessary to state, that, when printed in *Italics,* it is to be understood in the latter sense.

As a carriage is composed of various parts, and as all these parts must exactly correspond with one another, it is absolutely necessary that a working draft of the full size be completed before a carriage can, with propriety, be begun to be made. In the first place, it depends upon the construction of the *carriage,* what difference will be required betwixt the height of the fore and hind wheels to bring the perch to a proper level; the depth, from front to back, of the body, and the height which it is to be hung from the ground, is next required, in order to ascertain the proper length of the *carriage,* (that is) what distance the fore and hind axle trees are to be from one another. The particular manner in which the body is to be hung upon the *carriage* must also be fixed, in order to give the springs a proper degree of curvature. To obtain these particulars, a draft is made of the entire machine, and from it the master coach-maker at once sees what effect will be produced, and alters it until it pleases him: from this draft each workman takes his measures and makes his patterns, by which means every part of the work may be going on at the same time.

In making these drafts, the coach-maker is limited, in a certain degree, by the fashion of the day, at the same time he has it in his power to display his own taste and judgment in the construction; and his objects are to combine elegance with strength, and to obtain such a fitness of one part with another, that the carriage, when finished, shall appear as a whole, not wanting any thing that it ought to have, and not having any thing that it could apparently do without, endeavouring to give as much ease to the body part as possible, not to make any part heavier than absolutely necessary, and particularly to make it easy of draught, by having the best finished axle trees set in such an exact manner that the wheels may run perfectly free, following one another in the same tract.

The different branches of coach-making, as commonly practised, are,

1. Body making.
2. *Carriage* making.
3. Wheel making.
4. Smith's work.
5. Painting.
6. Trimming, and
7. Harness making.

Some of these branches may be subdivided, as in harness making there is included collar making and saddlery. The herald painting is done by workmen of great experience and taste, who do not generally perform any of the coarser work; and *carriage* painting is often done by a class of workmen different from those who paint the body; and in body and *carriage* making, the carving is sometimes done by workmen, who practise that particular department, although frequently by the body and *carriage* makers themselves. The glass frames and inside boxes are generally made by workmen constantly employed in that way, who, in general, also put on the plated or ornamental work, but are considered so nearly allied to the body makers as hardly to form a different branch.

I. *Body Making.*

Body making.

That is, the making the wood work of the body or shell, or that part containing the seat of every vehicle generally known by the name of carriage, whether open or close, and having either two or more wheels. This is considered the nicest branch of the art of coach-making, and very deservedly so; for to understand it thoroughly requires a knowledge of mathematics rarely to be met with in the lower classes, besides an accuracy and delicacy in the junctions of the various parts, and neatness in finishing, which no other part of coach-making so particularly requires. The variety in this branch is also much greater than in any other, as almost every carriage takes its particular name from the shape, size, or construction of the body, without reference to any other part of the vehicle, as for example, Landeau, Landeaulet, Coach, Chariot, Chaise, Phaeton, and Vis-a-vis, all differ only in the body, as all may have the same construction of *carriage*. In the present fashion of carriages, with the body made round or bulged on the sides, there are upwards of sixty frame joints in a chariot body, and scarcely one of them square. To find the exact length of each piece, and precise angle of each joint, (all of them differing from one another,) would require a knowledge of mathematics, not to be expected in ordinary workmen, and which, had they not been reduced to practical rules, would have proved an unsurmountable obstacle to the immense variety now to be seen in our modern carriages. But the principles once having been fixed, and practical rules deduced from them, the mechanic finds it easy to follow and instruct his pupil in the latter, without any knowledge whatever of the former.

The frame-work of the body is uniformly made of ash timber, the bottom (and roof of close carriages) of fir, as being lightest, the pannels of mahogany, (sometimes walnut tree,) as fittest from its nature to receive the paint, and more pliable to take the curved form which is required. The roof is covered with leather; the back and upper quarters are sometimes made of mahogany, but more frequently of fir, and covered with leather also. The joints of the frame-work are all put together with white lead ground in oil, and the junction of the pannels with the frame-work is strengthened by small blocks of wood being glued to both, and strips of canvas glued at small distances from one another across the reed of the wood, all over the inside of the pannels, reaching from the frame-work on the one side to the frame-work on the other. The curvature is given to the pannels by holding to the fire, or to a piece of iron made red hot, the side which is required to be hollow, and by applying water to the opposite side, by which the one side is contracted and the other side is expanded. When brought by this means to the desired form, they are fixed into grooves, or laid down with glue upon the frame-work until dry, and then cleaned off; the door pannels, besides this, are secured with plates of brass, attached firmly to the frame-work by screw nails. The utmost attention should be paid to use the best seasoned wood, as the smallest shrinking of any of the joints, or contraction of any of the pannels after being painted, injures the appearance, although not always materially, the security of the carriage.

II. *Carriage Making.*

Carriage making.

The *carriage*, as understood by coachmakers, is the frame-work which is necessary to support the body or shell of the machine. It in general consists of the perch or cranes which connect the bars upon which the hind and fore springs are fastened, and the other bars behind and before, upon which are fixed the spring-stays, the axles, the foot-board behind, and boot or budget before. Some carriages are now made without perches or cranes, but still the bars necessary for the above purposes are all that are technically called the *carriage*.

This branch is considered next in importance to the body-making, and in fact, in the knowledge of these two may be said to consist the art of coach making, as it is possible for workmen not regularly bred coachmakers to finish all the other parts, as wheels by wheel-makers, trimming by upholsterers, painting by ordinary painters, harness by saddlers, and so on; although there are peculiarities in each of these branches only applicable to coach-making. The *carriage*-maker, although not required to finish his work with that delicacy which is indispensible in the body-maker, has nevertheless to put together his joints with great precision and firmness, as the strength and durability of the whole depends much upon the *carriage*; for it undergoes more fatigue, and is therefore liable to fail sooner than any other part, the wheels only excepted. For this reason, the best seasoned wood must also be made use of in this branch, that none of the joints may shrink. In fitting the various iron plates and stays, great care must be taken that they be properly set to the required curves, and that their bearings be quite correct before being fastened, as otherwise, by the force of the bolts in screwing them on, the wood work would be twisted, and thereby not only disfigure the appearance of the parts, but materially weaken them. Smiths in general are so little aware of this, that the *carriage*-maker has often more difficulty in getting his iron work made perfect, than in executing his own more particular department. The *carriage* is always made of ash of the strongest growth, and perfectly dry; the joints are put together with white lead ground in oil, secured with bolts and iron plates, stays, hoops, and other iron-work, to the weight of from 230lb. in a light carriage to 370lb. in a heavy one, exclusive of axletrees and springs.

In fact, carriages, as they have been made for many years past, are, in every part, a combination of wood and iron, in order to produce a light appearance; the workmen being enabled, from the additional strength of the iron, to reduce the dimensions of the wood. The axle-trees are let into a groove in the underside of their respective bars of wood, (technically called beds) in order to secure steadiness; and they are fastened to the wood by iron hoops and bolts. The springs are made fast to their respective bars with screwed bolts, and the fore or under *carriage*, (that is, the frame work of wood to which the fore wheels are attached,) is secured to the main *carriage* by means of a strong iron bolt, called the perch bolt, upon which the axle of the front wheels turns independently of the hind wheels, thereby enabling the whole *carriage* to turn with ease, which it could not otherwise do.

III. *Wheel Making.*

Wheel making.

A carriage wheel consists of the nave, the spokes, and the rim. The nave is the centre wooden part of the wheel, which is turned in a turning lath, according to the taste of the workman; and into mortices in this, the spokes are driven which connect it with the rim. The rim is composed of several circular pieces of wood, called felloes, which are bored with holes to admit the outward ends of the spokes; the spokes being inserted in these holes, and wedged up, and the joinings of the felloes secured from passing one another, by internal connecting pins, called dowels, the wood work of the wheel is completed.

To secure the nave from splitting, two iron hoops are put round it; a narrow one at the end having the greatest diameter, which goes next to the carriage, and is called the in-head of the nave; and a broad hoop is put round the smaller end farthest from the carriage; this end is called the out-head of the nave; and the hoop, last mentioned, projects beyond the nave, in order to protect the end of the axletree of the carriage when running, and in the fore wheels it also serves the coach-man as a footstep to mount to the driving box or seat.

The chief difficulty in this branch is the execution of the work, as the angles of the joints are easily found, after which it only remains to draw a circle of the given diameter of the wheel, and work the felloes to it. When the workman, therefore, by experience, is enabled to put his work together in such a way, that, when the wheel is completed, all its parts bear equally against one another, the knowledge of his art is acquired; and, being provided with wood of good quality and well seasoned, he will produce a wheel of strength and durability. The naves are generally made of Scotch Elm, the spokes of Oak, the main stem of small Scotch Highland Oak being preferred, and for the felloes ash is reckoned best.

Each felloe has, at least, two spokes. Sometimes, in place of separate felloes, one piece of wood is bent, by means of steam, into a complete circle for the rim of the wheels. Wheels made in this way are preferable in appearance, but the difficulty of repairing them has prevented their being brought into general use. There are two

Wheels.

kinds of wheels, the conical wheel, and the cylindrical wheel; of the former, there are the single dished and the double dished, and of the latter there are the straight wheel and the cross dished wheel. These we shall describe: Let a line be supposed to be drawn from the centre of the nave, at the in-head, to the centre at the out-head, and let this line be called the axis of the wheel. A wheel is single dished, when the spokes, being all one length, and diverging outwards from the carriage, form, with the axis of the wheel, acute angles towards the out-head. A wheel is double dished when each spoke alternately forms, with the axis of the wheel, a more acute angle towards the out-head than the others; all of them, however, at the circumference, terminating in one plane at right angles to the axis. The straight wheel is so called when the spokes stand perpendicularly to the axis in the same plane. The cross dished wheel derives its name from each two alternate spokes, forming, with the axis, an isosceles triangle, the spokes being alternately joined nearer to the out-head and in-head of the nave, but all of them terminating at the circumference in one plane, intersecting the axis between the roots of the spokes. For the properties of the different kinds here described, see Wheel.

IV. *Smith Work.*

Smith work.

There is great variety of smith work necessary in making a carriage, and as much dependence is put upon the iron work: it must be not only of the very best quality, but worked in the best possible manner; upon these accounts, ordinary bred smiths are not, without a good deal of practice, fit to be employed by coach-makers, except in the coarser parts. In order to obtain as much perfection as possible in the execution of this branch of the work, it is subdivided into particular departments: some workmen being constantly employed in making springs, others at the axle trees, others at the steps, some at the iron work upon the wheels, some at the different plates and stays for new carriages, and others at repairs upon old work of all kinds. The springs ought to be of steel, of the best quality, well worked and properly tempered, which is the chief art of the spring-maker. In spring-making there is a considerable nicety required in proportioning the thickness and lengths of the different plates, giving them an equal temper and proper set, in order to produce a regularly increasing resistance to any weight that may be put upon them. It is by these means that a carriage can be made equally easy to be rode in with one person only as with four or six. The axletrees ought to be built of different bars of iron, laid along side of one another, and well welded together; for this purpose the tire which comes off old wheels is preferred, and the thinner it is worn down so much the better, as a greater number of plies are necessary, thus receiving a better mixture of metal, and, of course, greater uniformity and average strength. The finishing of the axletrees ought to be done with the greatest possible accuracy, as much of the ease of draught depends upon that circumstance, and as the greatest part of the noise made by carriages, when in motion, proceeds from the axletrees and boxes not having been properly fitted to one another. A considerable degree of correctness is necessary in making the footsteps, the opposite legs requiring to be of exactly equal lengths, the joints solid and smooth that they may fold with ease, and at the same time not be liable to fail soon or get loose. The variety of iron plates and fastenings requisite for a carriage is so great, that it would exceed our bounds to describe them all;

we shall, therefore, merely mention, that almost every piece of wood in the *carriage* is supported by, or strengthened with iron, attached to the wood work by bolts or rivets passing through both.

A considerable degree of art and practice is required in putting the tire or iron hoop round the rim of the wheels; the holes for the nails to fasten it to the felloes are first made, the bar of iron is then turned round and formed into a circle of the required diameter, and the two ends welded together; it is then heated all round red hot, and the wheel being laid with its face (that is, the out-head of the nave undermost) upon a flat piece of stone-work or metal plate, the iron hoops, from the great expansion occasioned by its heat, goes easily upon the wheel; the iron is then immediately cooled, and, by contracting, binds all the wood work together; the nails are then put through the tire into the felloes, and the wheel, being cleaned off, is finished. Formerly the iron was, very generally, put round the wood-work of the wheel in separate pieces, having nothing to fasten it to the felloes except the nails, but this practice has almost gone into disuse.

The iron work for carriages, which open at the top, requires to be made with more than ordinary nicety. It is sometimes done, along with the other iron work, under the coach-maker himself; but it is more generally procured, along with a vast variety of small hard ware articles, such as locks, hinges, nails, &c. from makers at Birmingham, who do nothing else.

V. *Painting.*

Painting.

The first process of painting the body of a carriage, is to lay it all over with any common colour, in which a considerable proportion of japan and a little spirit of turpentine are mixed. Of this colour the body ought to get three or four coats, always increasing the quantity of turpentine, and diminishing the Japan: this is called priming for the grounding. After this, two or three coats of filling up, or grounding, composed of powder ochre, japan, and a considerable proportion of turpentine, must be laid on, betwixt the two first coats of which, if there are any holes above the heads of nails, or other small indentations in the pannels, they ought to be filled up with white-lead, ground in turpentine, and mixed up with japanners gold size. When all this is quite dry and hard, the painter, having flattened a piece of pumice-stone on one side, applies it with water to the pannels, and by constantly and regularly rubbing them all over, produces a smooth even surface. After this the body is laid over with a colour, preparatory to that with which it is to be finished. If the colour is ultimately to be light, the preparatory colour must be light also, and the reverse if the colour is to be dark. In this part of the operation, which is called priming for the body-colour, two or three coats will be necessary. When all these previous coats are quite dry, the body-colour is laid over them: and it depends upon the particular colour and shade what number of coats will be necessary. One coat must succeed another, until the colour is quite solid, that is, until there is no cloud or inequality of shade perceptible in any part of the whole. After this, the best copal varnish ought to be made use of; and a body cannot be well varnished without six coats, and seven if the pannels are to be polished. Betwixt each coat of paint, the pannels ought to be smoothed with sand-paper; and after every coat of varnish, they ought to be well rubbed down with pumice-stone, reduced to a very fine powder, put upon a piece of woollen cloth, made up into a roll as hard as possible, and moistened with water, care being taken to smooth the pannels in this way as much as possible, without rubbing through the varnish. The body-colour sometimes requires to be laid with varnish alone, and sometimes it is necessary to mix a little of the colour with the two or three first coats of varnish. To produce a better black, the upper quarters, roof, and back of the body, are done with japan in place of varnish, immediately after the colour; and to render it capable of being polished, one or two coats of varnish are put above the japan. When armorial bearings or letters are to be painted upon the pannels, the proper time is betwixt the first and second, or sometimes betwixt the second and third coat of varnish, after which such a number of coats ought to follow as will render the whole pannels smooth over the arms, crests, or letters.

Pannels ought not to be polished sooner than a month after the last coat of varnish is given them; and if the carriage is used during that time, or even for a longer period, before polishing, so much the better, the varnish by exposure to the atmosphere acquiring a harder consistency, and consequently becoming more susceptible of a fine polish. The first operation in polishing is to rub down the pannels as before described, with very fine pulverized pumice stone and water, thereafter with purified rotten-stone, and afterwards by constant rubbing with the palm of the hand, using a small portion of dry rotten-stone to remove the gummyness off the skin. When by these means the pannels are brought to a good polish, a little flour and sweet-oil rubbed over, gives a smoothness to the whole, and finishes the work.

As herald painting depends entirely upon the justness of the eye, the neatness of hand, and the taste of the painter, we shall not presume to offer any general rule for the execution of the work; neither can we give such a description of its progress, as will enable our readers to make any estimate of the difficulties to be overcome in this department. We shall only observe, that long practice, great taste, and persevering attention, are required to attain to eminence.

In painting *carriages*, there is nothing particularly worthy of remark. The painter's chief care is to remove all grease or oil from every part before he begins to paint, and as the work goes on, to smooth every coat with sand-paper before laying the next. In ornamenting the bars and wheels, every thing depends upon the steadiness of the hand in drawing the lines clean and well defined. The *carriage*, after being painted, ought to get two or three coats of varnish, to give it a lustre corresponding to that of the body.

VI. *Trimming.*

Trimmin

The trimmer's business is to cut the lining, give directions for sewing it, to arrange the lace properly upon the different parts, and, after being sewed, to stuff quilt and to fasten it into the body. This requires a considerable dexterity and neatness of hand. Much of the comfort of a carriage depends upon its being well lined and stuffed; and as every part of it is immediately under the eye of the people within, if any thing is left undone, or any error committed, it cannot escape notice, nor fail to give a bad impression of the whole machine. The trimmer has also to cover and finish the glass frames, blinds, shutters, budgets, footsteps, trunks, imperials, and to do every thing belonging to the inside (and outside leather work) of the bodies of either close or open carriages, &c. The lining of carriages is generally made of woollen cloth, sometimes of Morocco leather, and sometimes partly of both, trimmed with lace manufactured for the express purpose, made a fancy pattern, or with family arms, or crests, as may be wished. There are also interlinings, made generally of cotton cloth, used for the purpose of preserving the principal lining.

VII. *Harness Making.*

Harness-making.

There is no difficulty in harness making, that cannot be easily overcome by attention and perseverance. One man in this line cuts out all the leather for the different articles required, and makes up the work, that is to say, tacks a sufficient number of plies together in a temporary way for the purpose desired. They are then delivered to the workmen to be sewed, an operation in which, by practice, some attain to great perfection, using merely the common awl. The workman makes his own thread, from yarn waxed with wrought rosin, putting at each end a bristle, for the more speedy entering the holes made by the awl. In sewing the fine parts of the work, such as the bridle, pads, &c. an instrument is used called a pricker, which is similar to a number of points of large needles fixed in a handle in a straight line at certain equal distances, with this instrument, the workman marks his seam, by pressing it down where the sewing is to be, and following with his awl every mark made by the sharp points, is enabled to make his stitches with the regularity of work done by machinery. The winkers of the bridle is made of double leather, having betwixt the plies thin plates of iron, to keep them in their proper shape. The pads are made in a similar manner; but the iron plates are considerably thicker and stronger, to preserve the bent form, which is necessary for the horse's back, and also to afford a steady fastening to the bearing hook and turrets, through which the reins run. In the under sides of these pads are placed cushions, similar to the pannels of riding saddles, to protect the horse's back. In dressing leather for harness making, the curriers are careful to adapt the different hides to the uses for which they are naturally best fitted; some for harness, which ought to be the strongest and thickest; some for strapping, which does not require so much strength, and others for reins, which ought always to be of the best and firmest quality, dressed down to a proper thickness, and perfectly well pressed.

VIII. *Saddle Making.*

Saddle-making.

The saddle tree is got from a professed saddle tree maker. It ought to be made of well-seasoned beech, strengthened with canvass glued all over it, and with thin iron plates. The seat part of the saddle is generally covered with hog skin dressed for the purpose, formed to the curve of the saddle, by being drawn, when wet, as tightly over the saddle tree as possible, and allowed to dry in that position. It is supported by girth web, or strapping, drawn very tightly over, and nailed to the saddle tree transversely; the straps for the girths are attached to the web, and the whole is then covered with serge, and stuffed with fine wool. The skirts are made of crop, being a kind of bend leather first dressed smooth, and afterwards stamped in a press. These are sewed to the seat part, and the whole is then stretched over the tree, and nailed down. The sides of the pannels that go next the saddle are made of tanned sheep skin, the under sides of serge. The two are joined together by an edging or facing of hog skin about one and a half inches broad, and then stuffed with wool, and quilted. When finished, they are fastened into the saddle with small tacks.

IX. *Collar Making.*

Collar-making

The ring, or front part of the collar, is made of strong grained leather, the back part of black sheep skin. These two are sewed together by one seam. The ring is then stuffed as hard as possible with straw endwise; after this the back part is also stuffed with straw, and faced or lined with baked hair, to present a more elastic and smooth surface to the horse's neck. The collar is then sewed together at the upper end, and, upon the junction of the ring, a small leather top is put. The flaps, or side pieces, after being stitched all round the outer edge, and joined together at both ends, are drawn on, until their inner edges lie in the groove made by the ring and back part of the collar, and are, together with a small cap to cover the joining of the back part, sewed to the collar all round. The cap serves partly as an ornament, and partly to prevent the rain running down the horse's neck at the sides of the collar.

* * *

Principal improvements.

We have now to draw the attention of our readers to some of the principal improvements made upon carriages, from the period at which they came into general use. There are two things which would naturally suggest themselves to the mind as fit objects of improvement in carriages—the comfort of the people who ride in them, and the facility of their draught; accordingly almost all the alterations attempted have been made with a view to the one or the other. We are led, in the *first* place, to notice the introduction of springs and braces, as perhaps the greatest improvement of any, their adoption having the double effect of rendering a carriage more easy to ride in, and more easily drawn. It is mentioned in the Memoirs of the French Academy, that the idea of applying springs to carriages was suggested by M. Thomas in 1703, and that he actually gave a drawing of a carriage constructed upon that principle. It appears, however, from the same work, that he considered it an improvement rather of a theoretical nature, than one capable of being reduced to practice. The result, however, has proved the contrary; and whether M. Thomas is really entitled to the invention or not, we consider it as the greatest improvement that has ever been made in the construction of carriages.

The next improvement we shall mention is the present method of constructing carriages to open at the top, giving at once all the advantages of a close and open carriage. Although it is not long since this improvement was introduced, yet it has so gradually come to its present state of perfection, that we are at a loss to say when the first carriage of the kind was constructed which could be said completely to answer the intended purpose. The old-fashioned long perch carriages having been found to occupy a large space in turning, the crane neck was introduced for the purpose of remedying this inconveniency. The crane neck, however, soon gave way to the short perch, which is found equally to answer the purpose of turning in a short space, although it requires the body to be hung higher. The axletrees, known by the name of Colling's patent, ought not to be overlooked as a material improvement: they undoubtedly facilitate the draught, and save great trouble in oiling; they are ingenious in their construction, and afford considerable security.

The carriages, without perches and without braces, which have been introduced of late, may be considered worthy of notice as a variety; but we confess ourselves partial to the former construction, both perches and braces having, in our opinion, considerable advantages.

Many other improvements in axletrees have been attempted, and some with tolerable success; and to insure the safety of carriages, there have been brought forward many inventions worthy of being tried, and we have no doubt that some of them may turn out beneficial.

One of the latest improvements is that of making *carriages* totally of iron, which, among other advantages, possesses that of having more strength than those of the ordinary construction of the same weight. The first of this kind was applied to a heavy stage coach, licensed to carry sixteen passengers, besides baggage, and has hitherto required no repair, although the coach has already run upwards of 90,000 miles with the same velocity as the mail coach. Metal wheels have also been introduced, and axles of a new construction; and, upon the whole, the carriage forms such a contrast to any other we have seen, that we have been induced to give a Plate and description of it.

Plate CXCVIII. Fig. 1.

Fig. 1. Plate CXCVIII. shews the body of a chariot hung upon a patent iron *carriage*, iron wheels, axletrees, and boxes: the latter, by a simple contrivance, is close at the out-head, by which means the oil cannot escape, and the fastening of the wheel being at the in-head, as will be explained afterwards, gives great security, and prevents the possibility of the wheel being taken off by any other carriage running against it.

Fig. 2.

Fig. 2. shews the arm of an axletree turned perfectly true, with two collars in the solid, as seen at G and H. The part from G to B is made cylindrical. At K is a screw nail, the purpose of which will be explained in Fig. 6.

Fig. 3.

Fig. 3. is the longitudinal section of a metal nave, which also forms the bush, for the better fitting of which to the axletree it is bored out of the solid, and made quite air tight upon the pin; and for retaining the oil it is left close at the out-head D.

Fig. 4.

Fig. 4. represents a collet made of metal, turned perfectly true, the least diameter of which is made the same with that part of the axletree M, Fig. 2, and its greatest diameter the same with that of the solid collar G, Fig. 2. This collet is made with a joint at S, and opens at P. Two grooves are represented at *q q*, *q q*, which are seen also at the same letters in Fig. 5, as also the dovetail *r* in both Figures.

Fig. 5.

Fig. 5, is an edge view of the collet, Fig. 4.

Fig. 6.

Fig. 6, is a longitudinal section of an axletree arm, nave or bush, and fastening. AB, the arm of the axletree, bored up the centre from B to E. CCD, the nave, which answers also for the bush. PS the collet (see Figs. 4 and 5) put into its place. *q q*, two steel pins passing through the inhead of the bush, and filling up the grooves in the collet. *w w*, a caped hoop, sufficiently broad to cover the ends of said pins, and made fast to the bush by the screws *w*, *w*. This hoop, when so fastened to the bush, prevents the possibility of the pins *q*, *q* from getting out of their places. *u u*, a leather washer, interposed betwixt the inhead of the bush and the larger solid collar of the axletree, to prevent the escape of oil at the inhead. K, a screw, the head of which is seen at the same letter, Fig. 2. This screw being undone, and oil poured into the hole, it flows down the bore in the centre of the axletree arm, and fills the space B, left by the arm being about one inch shorter than the bore of the bush, and the screw being afterwards replaced keeps all tight. In putting on the wheel, a little oil ought to be put into the space betwixt the collet PS and the larger collar. The collet PS being moveable round the axletree arm, and being made fast to the bush by means of the two pins *q*, *q*, revolves along with the bush, and acting against the solid collar G of the arm, keeps the wheel fast to the axletree, until by removing the caped hoop *ww*, and driving out the pins *q*, *q*, the collet becomes disengaged from the bush. The dovetail seen upon the collet at *r*, Fig. 9, has a corresponding groove cut in the bush to receive it, in consequence of which the wheel must of necessity be put on, so that the collet and pins fit exactly. These wheels very rarely require to be taken of, and they will run a thousand miles without requiring fresh oiling.

Plate CXCVIII. Fig. 6.

The spokes of the wheel, made of malleable iron, are screwed into the bush or nave at CC, Fig. 6, all round. The felloes, composed merely of two bars of iron, bent into a circle the edgeway, are put on, the one on the front, the other on the back of the spokes, which have shoulders on both sides to support the felloes, and all three are attached together by rivets through them. The space betwixt the two iron rings forming the felloes, should be filled up with light wood, and the tire then put on, and fastened to the felloes by bolts and glands clasping both felloes.

Plate CXCIX. Fig. 1.

Fig. 1. Plate CXCIX. shews a bird's eye view of the main *carriage* composed of four separate bars of iron, of the curves represented and connected together, by means of the hoops marked A, and reaching from the spring bar H H before, to the axletree bed I I behind. These two bars are, in this sketch, supposed to be of wood, although by making the hind axletree, and the transome plate before, of such shape and strength as requisite, these bars of wood become unnecessary also. There is neither footboard nor budget shewn in this draught, in order that the construction may be the better understood; and as these carriages can be furnished with either, or both, in any of the modes in common use, any description of the particular manner of attaching them is unnecessary. The two centre iron bars, composing the perch, are attached to the fore and hind bars, at B, B, B, B, by means of strong screw bolts in the solid. The nuts are seen at *b*, *b*, *b*, *b*. The two outside iron bars of the perch, are connected with the fore and hind bars, by means of three bolts at each of their ends C, C, C, C, which bolts also fix on the springs to the *carriage*.

The holes marked in the iron bars at D, D, D, D, are for fixing the spring stays by means of bolts.

F F, G G, is the wheel upon which the under *carriage* turns, and is fixed to the transome bar, in the usual way, by bolts, the nuts of which are seen at *d*, *d*. A stay, reaching from A 1 to A 2, makes steady the back part of the wheel; the ends of this stay forming the glands for the two hoops, and the middle being fastened to the wheel by the bolts *b*, *b*. The stays F G, F G, are fastened by bolts to the wheel at their ends, and to the transome bar in the centre with the bolts *e*, *e*.

At E is seen the nut of the perch bolt, which is screwed above the transome bar.

The gland of the hoop A 3 is formed into shackles for receiving the bottom braces for the body. The hoops *u*, *u*, *u*, *u*, *u*, are for making the hind axletree fast to its bed, by which means there is no necessity for having a hole in the axletree.

Fig. 2.

Fig. 2. is a bird's eye view of the under *carriage*. AB the locking wheel and transome plate; D C, D C, the fitchell stays; D D the sockets through which the splintree bar passes; H the front socket, and G the hind socket for the pole; E the upper end of the perch bolt. Neither the axletree, splintree, or splintree bar stays, are represented, to prevent confusion.

Fig. 3.

Fig. 3. is a side view of the fore or under *carriage*; AB the locking wheel; DCC the fitchell stays, made fast to the axletree at C in the same manner with gig stay fastenings; DAB, stays upon which the wheel rests, and which are made fast to the wheel and to the fitchell stays at B, and being also bolted to the fitchell stays betwixt

Coach-making, Coal.

A and D, act as a string to a bow, preserving the fitchell stays DCC in their curve against the pressure of the carriage; H, the fore, and G the hind socket for the pole; K, the splintree bar and roller bolt; E, the top of the perch bolt. The splintree stays are left out here for the same reason as before.

Plate CXCIX. Fig. 4.

Fig. 4. is a representation of the front of the fore or under *carriage*: MM the axletree; AB the locking wheel and transome plate; KL, the splintree bar; DC, DC the fitchell stays; MN, MN, the splintree stays; AM, B M two strong stays which connect the locking wheel and axletree at the shoulders; H the fore, and G the hind socket for the pole; EF the perch bolt.

In Figures 2, 3, and 4, the several letters apply to the corresponding parts.

We have been thus particular in our description of these improvements, from the originality and simplicity of the principles upon which they are constructed, and from the ingenuity of their execution. To have supposed it possible to have made a *carriage* without a mortice or tenon, or wooden joint of any kind, would, only a short time ago, have been considered as absurd, but in the preceding construction this has been completely accomplished; and we cannot help thinking, that this of itself must be of great importance to all carriages, but more particularly to those for public use, where durability is the principal requisite. But this improvement appears equally applicable to carriages generally, as from the nature of the material made use of, it is not additional strength alone that is procured, but variety of shape, elegance, and lightness; for we are assured that these carriages are at an average one seventh lighter than those built on the ordinary construction.[*] (v)

COAL is an inflammable substance, of a very black colour, somewhat shining, opaque, soft, dry, and light in comparison with any of the strata in which it is found. It occurs in beds varying in thickness from an inch to many fathoms.

It is used for fuel, and is found widely scattered over the globe. The most valuable and extensive beds of coal which have been found and wrought, are in Great Britain.

This mineral is never found in the primitive nor transition rocks, but in a third class of rocks very regularly stratified, the most common of which are, 1st, sandstone, 2d, slate clay; 3d, indurated or fire clay; 4th, argillaceous iron stone; 5th, limestone; and 6th, greenstone. Of the two first there are very many varieties, both in respect of colour and hardness. In the coal, and in all its accompanying strata, distinct organic remains are found belonging to the animal and vegetable kingdom: the greenstone, however, is an exception, as it is questioned whether any organic remains have ever been found in that rock. In the sand stones, the forms of large trees, and jointed reeds, (arundo,) are found abundant, but impressions of shells are very rare. In the slate clay, the forms of large trees are seldom seen, but innumerable impressions of leaves, ferns, and moss plants, (cryptogamia,) are found in the area of a few feet; and it is remarkable that where the forms of shell fish are found in this kind of strata, they are never of the same substance as the matrix, but are always of argillaceous iron stone embedded in the slate clay. In the fire clay, a branched tree of singular appearance is most frequently found. The iron stone abounds with forms and impressions of plants, but more frequently with the forms of shell fish of the class

Coal.

Mytelus. The upper part of the coals have frequently the distinct impressions of large trees, and the lime stone is in many instances a congeries of marine animals. In the sand stone, where forms of trees are found, the bark or exterior part is of coal only, which is very thin, of a bright shining black colour, and cubical.

From the very regular stratification of this field of the mineral kingdom, the vast beds of inflammable matter it contains, the great abundance of organic remains found in it, and as none of the primitive or secondary rocks are connected with the strata, it has therefore very properly been denominated by the celebrated and great mineralogist Werner, *the independent coal formation.*

Coals, with their various accompanying and parallel strata, are found lying in every inclination to the horizon. Some of them are vertical, others nearly horizontal, but never absolutely so to any considerable extent. The most common dip or declination is from 1 in 5, to 1 in 20. A bed of coal, as to its form or shape, considered in the abstract, is generally somewhat semicircular or semi-elliptical; and is the segment of a flat bason. There are some instances where the bason shape is complete, the slips and dislocations of the strata which occur, derange the general form; still, however, each segment evidently partakes of the bason form. In some few instances the form is quite the reverse, as if the coal bed was formed by being revolved round a cone. The vertical coals do not partake of this bason shape, which might be easily inferred from their peculiar situation.

We are inclined to conclude from practical observation, that the forms of coal fields depend upon the shape of the primitive or secondary rocks, upon which they certainly rest. Coals, we believe, and as far as our investigation goes, are never found in veins in the mountain rocks, similar to those in which metals occur.

The *coal formation* is found chiefly in the northern hemisphere, and abounds in the countries lying nearly in the same latitudes with Great Britain. Coal is found in Siberia, Canada, Newfoundland, and Cape Breton; also in France, Germany, and Sweden. It is likewise said to be found in the northern parts of China. In the southern hemisphere, it is stated to be very abundant in New Holland, but we have no distinct accounts of coal in the continent of Africa.

As to the surface of the ground under which coal is found, it is much doubted if any peculiar character exists, (as has been advanced by some mineralogists) in Great Britain. It is found under every variety of surface, excepting the wild and rocky mountains. It is, however, to be remarked, that a great part of the valuable and extensive coal field of South Wales, is found in a mountain district, and the strata of the coal field form these mountains even to their summits, which are elevated not only very much above the level of the sea, but also above the adjoining country. These hills are smooth and covered with verdure, and present no rocky cliffs on account of their comparatively soft strata. Hence the existence of coal in any district of country, not mountainous, cannot be deduced from the appearance of the surface, but rather from the relative situation of the particular district with respect to the rocks of the primitive or secondary class.

Of coals there are various species, viz.

Cubical coal.

1. *Cubical Coal*.—Is black shining, compact, and moderately hard; when wrought, it turns out in quadrangular masses, and when broken small, the fragments are

---

[*] We are happy to have it in our power to lay before our readers an account of the great improvements which have been recently made upon carriages, by H. R. Brown, Esq. Edinburgh. The uncommon elegance of the carriages which he has constructed, and the great ingenuity which is displayed in the formation of his patent axletree and wheels, will do more to recommend them to notice, than any praise of ours; and we have no doubt but that the inventor and patentee will be rewarded by the patronage of the public. Ed.

cubical. The lamellated structure, or what is termed the reed of the coal, is always parallel to the bed or strata upon which it rests, as is the general case of all coals, with a very few exceptions. Of this coal there are two kinds, the caking coal, and the open burning coal. The caking coal of the best kinds, however small when kindled, undergoes a semi-fusion, and unites into a solid mass. The open burning coal, burns more rapidly than the former, with much flame and heat; the caking coal is very abundant in England, the other is abundant both in England and Scotland. The cubical coals which unite when set on fire, are known by the name of caking or smithy coals; the open burning coals by the name of rough coal, cherry coal, and clod coal.

The Whitehaven caking coals, in the west of England, according to Kirwan, contain

Carbon,	56.8
Asphalt and Maltha, the former predominating,	43
	99.8

Specific gravity 1.250.

Slate coal.

2. *Slate Coal*—Is black, compact, and much harder than the first species; dull in the colour; in working turns out in large quadrangular masses, which can with ease be split into very thin pieces, similar to slates, hence the name. This coal is open burning, and produces much flame and smoke; it contains a greater proportion of white ashes than the cubical coals. Some of the inferior kinds of this coal burn with difficulty, and produce a great quantity of white ashes. This coal is commonly known by the name of splint coal, and, according to Kirwan, contains

Carbon	47.6
Maltha	31.6
Ashes	20.8
	100.0

Specific gravity 1.426.

Glance coal.

3. *Glance Coal*—Is black, with bright metallic lustre, and brittle; it has the external characters of the preceding species of coals, but the chemical properties of charcoal, hence termed by some mineralogists *native mineral carbon*. It burns with considerable heat, with a blue lambent flame, produces no smoke, and leaves a small proportion of ashes; it appears to have a portion of sulphur in direct combination, so that in burning it gives out a most suffocating effluvia, it produces no soot, but on the contrary whitens the places where the fumes are condensed. This kind of coal abounds in Ireland, and is known by the name of Kilkenny coal; it is the blind coal of Scotland, and the malting, or stone coal of Wales. This coal approximates to the graphite or plumbago species, and in some instances passes into it. From the trial of several specimens, it contains of carbon from 72.05 to 90.00. Specific gravity, 1.526.

Cannel coal.

4. *Cannel Coal*—Is black, with little lustre; in working turns out four-sided columnar, breaks with a conchoidal fracture, in any direction, like pitch, ignites very easily, and burns with a very bright flame like a candle, from which it derives its name. It is found very abundant in the coal field at Wigan, in Lancashire, where there is an entire stratum of it about four feet thick, without a mixture of any other coal. It produces very little dust in working, and does not soil the fingers as the other coals do; varieties of this coal are found in Scotland, forming frequently part of the thickness of the common coals. What is termed pitch coal by some mineralogists, is only a variety of this species. The cannel coal, when first kindled, decrepitates very much, throws the burning splinters to a distance, and is on this account dangerous; it is said that this fault is corrected by immersing the coals for some time in water, previous to their being used for fuel. In Scotland this coal is termed parrot coal, or bottle coal.

It contains, according to Kirwan,

Carbon	75.
Maltha	21.7
Ashes	3.12
	99.82

Specific gravity 1.232.

Sulphureous coal.

5. *Sulphureous Coal*, is of a dull black colour, mixed with a great proportion of pyrites. Though pyrites is found in distinct pieces in coal, this occurrence does not constitute it a sulphureous coal, because the pyrites can easily be picked out; but sulphureous coal, properly so called, has the pyrites so interwoven with its texture in small veins, or so intimately combined with the principles of the coal, that the sulphureous parts cannot be separated. It is very unsafe to work such coals, because if any quantity of the small coals produced in working is left below ground, a decomposition ensues, heat is generated, and the mine is set on fire, of which there have been many instances. When laid in heaps above ground the same result ensues, hence it is very unsafe to be put on board a vessel for a voyage of any considerable length.

This coal is very heavy, and yields a large proportion of ashes.

Culm coal.

6. *Culm Coal*, is of a dull black colour, small and dusty, by some mineralogists it is reckoned a distinct kind of coal, at least such is said to be the case in Sweden. What is termed culm in Great Britain, is the refuse or small dusty coal produced in working the common coals; it contains much earthy matter, will not kindle in an ordinary fire place, but produces a considerable heat and flame in a furnace, where a strong current of air is introduced; it also produces a very great proportion of ashes. In England it is exempted from the high duty imposed on the other coals.

Bovey coal.

7. *Bovey coal*, or bituminous wood, is found in alluvial land, though some mineralogists affirm that it is found in the rock stratification. It is composed of trees, reeds, and rushes embedded in the alluvial earth, the form of the trees, the ligneous and fibrous texture, being, in most cases, distinct; their texture is impregnated with petroleum, and combinations of the sulphuric acid. When first dug up, the fibres are flexile; in burning, it produces little heat, and a very unpleasant smell, and is only used where other kind of fuel is scarce and in high price. In England it is found in greatest abundance at Bovey near Exeter, from which it derives its name; it also abounds in many parts of the continent, particularly in Germany.

Two hundred grains of Bovey coal, according to Hatchett, yielded,

Water turbid and mixed with bitumen	60 grains.
Thick brown oily bitumen	21
Charcoal	90
Hydrogen gas, carbonated hydrogen, and carbonic acid	29
	200

According to Professor Jameson there are five subspecies of this inflammable matter, classed under the name of *Brown coal*.

The foregoing are the principal kinds of coal known in commerce, and used for economical purposes. In each kind various shades of difference exist, both with respect to texture and quality.

With regard to the economical uses of the coals be-

Economical uses of coal.

fore mentioned, we shall state them briefly: The cubical and slate coals are chiefly used as fuel in private houses, and in all manufactories where a strong heat is required; the caking coals are most suitable for smith's fires; when any of these coals are made into coaks, they produce an intense heat in the blast furnace for the making of iron, being used with success in place of charcoal; the slate coals of the best kinds suit this purpose excellently, as from their strong texture they bear a heavy load of iron stone, and a strong blast.

The coals of South Wales employed in the making of iron, contain less volatile matter than either the English or Scotch coals; so that in producing a ton of pig iron, only about half the quantity of coals is requisite, as a given quantity contains a great proportion of carbon. That able and practical chemist, Lord Dundonald, whose genius merited a high reward, invented a process by which the volatile parts of the coal were condensed, producing volatile alkali, oil, and tar; the coals thus distilled were converted into excellent coak, and applied for the purpose of making iron; this beneficial plan has only been adopted in a few instances, particularly at Coalbrookdale in England, and at Muirkirk in Scotland.

For the production of intense heat and flame in a furnace, the slate coals are most suitable, as, by keeping open, they admit a constant supply of air, which preserves a vehement combustion; on this account they are in great request by the Scotch and Irish distillers.

Glance coal is used in Ireland as common fuel, and sells at a high price. It is much used for drying grain and malt; to these it imparts a fair colour; it is for this latter purpose that the Welsh and Scotch coals, of this kind, are chiefly used. It is also used for the burning of lime, for which it is very suitable.

Cannel coal is chiefly used for common fuel: that which is found in Lancashire admits of being turned on the lath, and is made into a variety of utensils and ornaments, being susceptible of a very high polish, nearly equal to that of jet; and of the various coals it is said to be the most suitable for producing the coal gas used for lighting upl arge manufactories.

Sulphureous coal is but very little used, being so dangerous to work; it is only suitable for the burning of lime, the making of salt, or for producing sulphate of iron.

Culm is used for burning of lime, making of salt, and for steam engines; it sells at a very low price. There is but a small consumpt for this coal in comparison of what is produced annually in the mines.

Bovey coal is only used as common fuel by the poorer classes of the community, where better fuel cannot be had.

Origin of coal.

With respect to the origin of coal, naturalists have in general concluded that it is from the vegetable kingdom, particularly from the result yielded by distillation, which is as follows:—

Watery phlegm,
Volatile oil,
Volatile alkali,
Thick oil,

which last, on being rectified, produces a transparent thin oil; but it is remarkable that this oil, by exposure to the air, becomes black like animal oils.

Various theories have been brought forward regarding the formation of coal, and in these much learning and ingenuity have been displayed. From the incontestible and evident traces of vegetables found so very abundantly in the strata of the coal fields, together with the above analysis of coal, and the strong light and heat evolved in burning, we are inclined to concur in idea with those who conceive it to be of vegetable origin. All the patient investigation of mankind regarding this point of natural history, will never produce an absolute and satisfactory conclusion on the subject, there being such insurmountable difficulties, particularly when we consider that many of the vegetable remains found in the coal strata of Great Britain, belong to classes of plants which are now found only to exist in the equatorial regions; a fact which favours a theory brought forward by some naturalists, viz. that at the great and universal deluge, the poles of the earth were changed considerably from their position. The formation of our globe, together with the causes which produced the various convulsions and dislocations which have so evidently taken place in the mineral kingdom, must ever remain veiled in a dark impenetrable cloud. We must, however, conclude, that this vast magazine of fuel is most evidently placed by an all-wise Being in the bowels of the earth, in such positions and situations, as are most apt and convenient for the use of man, and where his industry and ingenuity may be exercised.

Coal being an article so indispensibly requisite for mankind in civilized society, it is of great importance to learn every particular regarding its natural history, so that its existence may be traced, by a distinct analogy, in countries widely separated. And when coals are found, it is also very important that the most approved practical and œconomical plans may be applied for working them to the best advantage. The mode of searching and boring for coal; the detail of the most approved plans now used for working the mines; descriptions of the dislocations and obstructions which most frequently occur in coal fields; together with the general economy connected with the working of coal mines, will be given under the article MINE. COBLENTZ, the *Confluentia* of the ancients, is a town of France, in the department of the Rhine and Moselle, situated at the confluence of these two rivers, from which circumstance its name is derived. Coblentz forms a perfect triangle, one side of which extends along the Moselle, and the other along the Rhine. The streets are in general very regular, and are well paved and lighted, and the houses, which are chiefly of three stories, are built of stone. The long street of Rheinthor, which traverses the whole town, is reckoned the finest, though it is not uniformly straight.

There are two collegiate churches at Coblentz, viz. the churches of St Castor and St Florin; three parish churches, viz. that of the Court, that of Notre Dame, and that of St Castor; besides the church of St John, which formerly belonged to the Jesuits, and four convents of monks. The collegiate church of St Castor is very old, and the place on which it stands was once an island in the Rhine. The large and solid dome is supported by columns of the Corinthian order, which are admired for their lightness. In the choir, which is very beautiful, are four paintings by J. Zick, representing the history of St Goar and St Castor. Above the choir, and near the principal altar, which is ornamented with a cross of gilt copper, from seven to eight feet high, are the tombs of several archbishops.

The church of St Florin is next in point of antiquity to that of St Castor. The choir is adorned with fourteen paintings, by J. Zick, representing the passion of our Saviour.

The parish church of Notre Dame is large and well lighted. It is distinguished by its spires, which are very lofty, and of uncommon architecture. On the southern side of one of these is a dial, which, along with the hour of the day, shews the phases of the moon. This church has several beautiful altars of marble, but is too narrow in proportion to its length.

The convent of the Dominicans, situated on the Moselle, and built in the 15th century, is the only one worthy of notice. The church is fine, and its principal altar magnificent. It is built wholly of stone, and is adorned with several very fine sculptures.

The gymnasium or college, is a very fine building, situated in the middle of the town. By the large square which is before it, by its two entrances, and by its proximity to the church of St John, which it touches, it adds greatly to the beauty of the street called *Firmung-strasse*.

The bridge over the Moselle, built of stone, was erected in the 14th century. It is 528 feet long, and has 14 arches sufficiently high to permit small vessels to pass below them, without lowering their masts. The bridge of boats, or the flying bridge, by which passengers cross the Rhine to Thal-Ehrenbreitsten three times every hour, is a very interesting object.

The palace of the electors of Treves was formerly situated on the opposite side of the Rhine, at the foot of the rock on which the ruins of the castle of Ehrenbreitsten once stood; but from the danger and inconveniences of this situation, a new palace was built about 25 years ago, on the left bank of the Rhine, a little to the south of the town. It fronts to the west, and has two fine circular wings. The central building is three stories high, and has a fine projecting entrance, consisting of eight columns of the Doric order, supporting a balcony, and capable of receiving carriages in the time of rain. The back front, towards the Rhine, is ornamented with six columns, which support a bas relief of beautiful workmanship. The whole building is surrounded with an avenue, planted with fine trees. This magnificent palace, however, is now in ruins, and is used as barracks.

At a short distance to the south west of the town is the Chartreuse, which is situated on the top of several mountains, which rise insensibly one upon another. The mountain upon which it is built, consists of clay, which is used for pottery ware, and from the top is to be seen one of the most beautiful and extensive prospects. This monastery is now in ruins, and is inhabited only by an innkeeper.

The other objects of curiosity at Coblentz, are the fort of Marceau, on the road to Andernach, the tombs of General Marceau, and General Hoche. There is also another monument erected to General Hoche, not far from Weissenthierne, opposite to Neuwied. The *Dikasteriul-Bau*, and the theatre are also fine buildings.

On the opposite side of the Rhine stands the Fauxbourg, called Thal, and the celebrated fortress of Ehrenbreitsten (*Heribertii Saxum.*) This fortress, which is now in ruins, is situated on the summit of a stupendous rock, which rises 800 feet above the bed of the river. Before the demolition of this fortress, it was considered impregnable, when defended by a competent garrison. It was ascended by three difficult and winding paths, one of which is now broken;—it communicated with Coblentz by tunnels cut through the solid rock, and it was supplied with water from a well 286 feet deep. The view from the top of the rock is considered as the finest on the banks of the Rhine.

Coblentz is surrounded with mountains covered with vineyards, and a great deal of wood grows in the arrondissement. It carries on a small commerce in the productions of the country, and the only manufacture is one of Japanned tinned goods. Population 10,000. E. Long. 7° 4′, N. Lat. 50° 24′. See *Coblentz ein hist. topograph.* Versuch *von Lessoux*, *Coblentz*, 1803. (*π*)

COBOURG, *Melocabus*, or *Coburgum*, a town of Germany, in the kingdom of Saxony, situated upon the river Jesd, in a valley between two mountains. The town and the suburbs are surrounded with a wall. There are here four churches, and likewise a college, founded in 1597 by John Casimir duke of Saxony, and endowed by him with many valuable privileges. In the church of St Maurice is the tomb of the Duke John Frederick. The other objects deserving of notice is the collection of prints belonging to the prince, the cabinet of natural history and medals, the ducal garden, the arsenal, and the new promenade. The inhabitants work a great deal in petrified wood, which is found in large quantities in the surrounding country. E. Long. 10° 58′ 0″, N. Lat. 50° 15′ 18″. (*w*)

COCCUS. See ENTOMOLOGY.

COCHIN, COCHIM, or COCCI, a seaport town of Hindostan, on the coast of Malabar. It received its name from the small river Cocci, which formerly discharged itself there into the sea. In the year 1341, when the sea threw up the island of *Vaypi* or *Baypin*, which is about 13 miles long and 1 broad, on the north side of Cochin, the torrents from the Gauts broke through the banks of the river, swept away the village, and formed a huge river, a lake, and a harbour of such capacity, that large vessels can anchor in safety on the north side of Cochin when the river throws itself into the sea. The enormous hills of sand which the sea throws up in June and July, are washed away by the river in August and September, and, at these seasons, the struggle between the torrents and the ocean often alters greatly the appearance of the coast. The inhabitants of the island of Vaypi begin their æra at the period of its origin.

The city of Cochin was built by the Portuguese in the 10th century, after the arrival of Vasco de Gama at Calicut. It is nearly of a semicircular form, and is about a mile and a half in circuit. Six large bastions and a cavalier defend it on the landside, and an irregular work on its eastern side; while a strong wall, terminating towards the east in a ravelin before the cavalier, and having loop holes for the admission of small arms, protect it on the water side. In 1778, the governor, Adrian Moses, repaired the fortifications of the citadel, and supplied it with new ditches, bridges, batteries, and bastions. A wet ditch encircles the works, and before it is a covered way and a glacis. There is also a ravelin between the bastion Gelderland, and the beach.

Cochin is intersected with beautiful streets, which, though wide and cleanly kept, are not adorned by many handsome houses. The principal public buildings are the government house and the church. The government house, the residence of the governor, is a spacious and airy mansion fronting a large plain. The mainguard stands opposite to it, and on the left side are the barracks for the governor's body guards. The church is a large and oblong building. The fine cathedral, which was built by the Portuguese, was employed by the Dutch as a store-house, in which they kept the sugar from Batavia, the cinnamon from Ceylon, together with the nutmegs, cloves, iron, copper, cordage, rice, pepper, and various other articles of merchandise, which they sold to the native princes. There is also here a city hotel, annually farmed out by the goverment, where strangers are provided with lodgings. Cochin has three gates, one to the north, leading to the river, called the Water Gate, another to the east called the New Gate, and another to the west called the Bay Gate.

Although Cochin is not fortified according to the rules of art, it could only be taken by a regular siege. Approaches could only be made from the south, where there is a dry and level plain; for to the east, as far as the rivers, there are several morasses, which would greatly impede an attack from that quarter. The security of the city would be much increased by destroying the woods, which lie about a mile and a half south east from the town, and also those which cover the southern part of the island of Vaypi. The enemy would thus be deprived of the materials for constructing their batteries, and for filling up the morasses and ditches in their way. Cochin was taken by the English in 1795. E. Long. 75° 16′ 15″, and N. Lat. 9° 56′ 30″. For further information on this subject, see Baldæus's *Description of the Coasts of Malabar and Coromandel,* p. 111—136, Amsterdam, 1672. Situation. COCHINCHINA, a kingdom in Asia, extends from about the 10th to the 20th degree of North Latitude, and is bounded by the kingdom of Tonkin, or Tung-quin on the north; by the gulf of Tung-quin, and the Chinese sea, on the east; by the Indian ocean on the south; and by a ridge of high mountains, which separate it from Cambodia, on the west. It stretches along the side of the Chinese sea from 600 to 700 miles, its breadth bearing no proportion to its length; for, in general, its breadth, from east to west, does not exceed a degree, and in many places is not above 20 miles. The whole country is intersected by rivers which descend from the mountains, and which, though not large, are very favourable to inland navigation. The climate is healthy, similar in temperature to Tung-quin, but milder by its vicinity to the ocean.

Productions. The face of the country exhibits but few marks of tillage, nevertheless it is not unfruitful. In the rainy season, which lasts during the months of September, October, and November, the low lands are subject to inundations from the mountains, which continue for three or four days at a time. These, like the overflowings of the Nile, contribute very much to the fertility of the country. Of rice, they have generally two plentiful crops every year, one in April and the other in October; that grain requiring no other manure than the mud deposited by the torrents which issue from the mountains. Oranges, bananas, figs, pine-apples, greavas, pomegranates, and other fruits of inferior quality, are produced in great abundance in all parts of the country. Indeed all the fruits of India, and many of those of China, are to be found here in the greatest perfection. They have also good yams, and plenty of a sweet kind of potatoes. Sugar canes and tobacco are cultivated in large plantations. The juice of the former, after undergoing a partial refinement, is exported to China in cakes; but the latter is consumed in the country, for persons of every age and rank indulge in the habit of smoking.

The timber of this country is the finest in the world, and it may be said to afford the same supply to China that Norway does to Britain. Their oak, pines, and teak, are admirably adapted for ship-building; and their mountains also abound with a species of wood, which, from possessing the power of preservation under earth and water, is called by the natives *the incorruptible tree.* Their forests also produce a variety of scented woods, as the rose-wood, eagle wood, and sandal wood, all of which fetch very high prices in the China market. Their cinnamon, though of a coarse grain, and strong pungent flavour, is preferred by the Chinese to that of Ceylon. On the mountains of the Kemois there grows a tree, the wood of which is most fragrant, and is supposed to be the same with *lignum aloes.* Being accounted the most valuable wood in the country, it sells from 5 to 16 ducats per pound, and the profits belong to the king. But in China and Japan it fetches not less than 200 ducats per pound, and is formed into beds for the emperor and nobility. It is also used in the funeral piles of those Indians, who still continue to burn their dead. Some gold and silver mines, as well as some species of diamonds, have been found in this country, but the latter are not deemed so valuable as pearl. On coral and amber they set a high value.

Domestic animals and food. Of domestic animals, they have almost every species except sheep. The country abounds with small horned cattle, short-legged hogs, kids, ducks, and fowls. Their cattle being of a small breed, do not supply them with much milk; but they seem to have no great desire for that article, for they do not give it even to their children, whose food consists chiefly of rice, sugar-cane, and water melons. Like the Chinese, they feed on dogs, and frogs are also a very common article of food. To the inhabitants of the coast, who form the greater part of the population, the sea is a never-failing source of sustenance; and the great extent of sea coast enables them to avail themselves of the inexhaustible stores which that element supplies. For catching the fish they employ a net, and sometimes wicker baskets; and vast quantities of flying fish are taken by sinking deep earthen jars with narrow necks, baited with pork, or the offals of fish. The great body of the people, like the Chinese, have but two meals in the day, one about nine in the morning, the other about sunset; and in the dry season these are usually eaten before the doors of their cottages, on mats spread in the open air. They do not cultivate the grape, but drink a liquor brewed from rice.

Wild animals. The wild animals are such as are common to India, viz. the boar, tyger, rhinoceros, elephant, buffalo, with abundance of deer. In the forests of this and the neighbouring countries, the elephants are said to be of a larger size than in any other part of the world; and the hunting of the elephant, the tyger, and the buffalo, is an amusement with which the sovereigns entertain foreign ambassadors. On these occasions they celebrate the *royal feast of elephants,* which has probably given rise to the report that the Cochinchinese feed on the flesh of those animals.

Sea-slug.

Curious nests.

The numerous little islands, which lie along the coast of this country, afford an article of luxury in very great demand in China, called the *Trepan* or *Bichos da mer*, which is a species of sea slug. Vast quantities of this little animal are also collected on the northern coast of New Holland, and carried to the Chinese market. Captain Flinders, who was sent out on a voyage of discovery to that coast, learned that not less than sixty vessels made an annual voyage regularly for the sole purpose of collecting these marine productions, during the preceding twenty years. After being detached from the rocks, they are opened, washed in fresh water, and boiled, then dried in the smoke of green wood, in nearly the same manner as our red herrings are prepared. In the same islands, running parallel with the coasts of Cochinchina, and known in the charts by the name of the *Paracels*, another valuable article of export is found, namely, those celebrated nests made by a small bird about the size of our swallow, and cemented with a kind of gum, the different layers of which may be separated in the same manner as the coats of an onion. When this gum has been dissolved in warm water, it is used for seasoning fish, and dishes of various kinds; to sauces it also communicates an exquisite taste, and hence it becomes a valuable article in the Chinese market. These islands also abound with turtles, of so delicate a flavour, that, in order to obtain them, the inhabitants of this and the neighbouring countries fight desperate battles.

Origin.

Until a few centuries after the Christian æra, Cochinchina formed a part of the Chinese empire; and the general features of the natives, particularly in the northern provinces, their customs, their written language, their religious opinions and ceremonies, still indicate their Chinese origin. They also, in many respects, resemble the Tung-quinese, with whom they have a common origin, and from whom they differ very little in their mode of life. Although it is the tendency of all revolutions to change the character and manners of a people, and although that observation in many respects holds true, with regard to the difference betwixt the present, and the former manners and customs of the Cochinchinese, yet, in their diet and superstitions, their marriages and funeral ceremonies, their games, music, and entertainments, and in the greater part of their ordinary life, they exactly resemble the people from whom they have been separated. Instead, therefore, of entering into a minute description of these, we shall refer the reader to the article China, and confine our observations to those manners and customs, which may be termed peculiar to this country.

Appearance of the natives.

The general appearance of the Cochinchinese is by no means engaging to the eye of a stranger. The women have no pretensions to beauty; but, unlike the morose and secluded Chinese, they do what they can to compensate for the want of personal charms by a lively and cheerful temper. Both sexes have coarse features, and dark complexions; and their universal custom of chewing areca, or betel, by reddening the lips and blackening the teeth, gives them a disgusting appearance. They are, however, represented as gentle, hospitable, enterprising, and industrious. Few crimes are to be found among them: robbery and murder are unknown. A stranger is every where received with the most eager curiosity, but at the same time with the greatest benevolence and hospitality.

Dress.

The dress of this people has undergone a considerable change from that of the Chinese. Indeed the dress of the men differs very little from that of the women, being chiefly confined to a jacket and a pair of trowsers; and both sexes go bare-legged, and generally bare-footed; but the women in the higher ranks wear a kind of sandals or loose slippers. Their long black hair, like that of the Malays, is usually twisted into a knot, and fixed on the crown of the head. This is the ancient mode in which the Chinese wore their hair, until the Tartars, on the conquest of the country, compelled them to the ignominy of shaving the whole head, except a little lock of hair behind. Short hair is therefore now accounted a mark of vulgarity, and even of degeneracy.—A loose cotton frock, of a brown or blue colour, reaching down to the middle of the thigh, and a pair of wide black nankeen trowsers, compose the usual clothing of the women. When they wish to appear better dressed, they put on three or four frocks at once, of different colours and lengths, the shortest being uppermost. Some wear handkerchiefs tied round the head, in the shape of a turban; others have hats, or caps, of various materials, for protecting their faces against the rays of the sun; and for the same purpose they use umbrellas made of China-paper, or of the leaves of palms, and sometimes fans made of feathers. Their children, till the age of eight or nine years, have no clothing, and yet appear uncommonly stout and healthy.

Customs and manners.

The following account of a public dinner given to the officers of British ships, and other gentlemen who composed an embassy to this country, may serve to illustrate the manners of the inhabitants. "As none of the houses in the town were large enough for the accommodation of so numerous a party, the Governor issued his directions for building a spacious shed, which, by the help of the ever-ready and useful bamboo, was finished in the course of a few hours: the roof and the sides were covered with thick close mats. Within this shed was placed a row of little tables, with forms on each side, to which might sit down conveniently from twenty to twenty-four persons. In China it is the custom to cover these little square tables so completely with dishes, or rather bowels, that no part of their surfaces shall be seen; but the Cochinchinese seem to have improved upon the liberality of their highly polished neighbours, by not merely covering the table, but by piling the bowls in rows upon each other three or four in depth. Of table linen, knives, forks, bottles, and glasses they make no use; but before each person is laid a spoon of potters ware, and a pair of porcupine quills or small sticks of bamboo, of rose or sandal wood, sometimes tipped with silver or *tootanague*, of the same kind in every respect as those used by the Chinese, and known to the English under the name of *chop-sticks*. The contents of the bowls are preparations of beef, pork, fowls, and fish, cut into small pieces, mixed with vegetables, and dressed in soups and gravies, variously seasoned, and composed of various materials. We had nothing roasted, nor prepared in the dry way. Neither wine nor spirits, nor fermented liquors of any kind, nor even water, were served round during the time of eating; but when dinner was over, Chinese *seau-choo* was handed about in little porcelain cups." Barrow's *Voyage to Cochinchina*, p. 287.

Degradation of the female character.

In this, as in all other countries where civilization has made but little progress, the females are doomed to the most laborious occupations. They may be seen standing from morning to night, in the midst of pools of water, up to the knees, occupied in transplanting rice. They undertake the labours of tillage, and the various employments of agriculture; while those who live in the seaports, besides the management of their domestic concerns, undertake the superintendance of the various branches of commerce. They even assist in constructing and repairing the cottages; they conduct the manufactures; they ply the boats in the rivers, and in the harbours; they carry the articles of produce to market; they weave the cotton into cloth, dye it, and make it into dresses for themselves and their families. But nothing can be a stronger proof of the degradation of the female character, and the unceasing labour to which they are doomed, than the proverbial expression in the country, "that a woman has nine lives, and bears a great deal of killing." The younger part of the males are compelled to enrol themselves in the army; and the rest are employed in fishing, in felling timber, in building and repairing ships and boats, and in preparing articles of export for the China market; but leaving always a considerable portion of time for some favourite amusement.

Amusements.

An idea of the nature of their amusements will be best formed from the account which Mr Barrow gives of an entertainment prepared by the inhabitants, on the fourth of June, in honour of the birth-day of the king of Great Britain. "We were conducted from the place of landing, to a temporary building, on a larger scale than that which we had hitherto occasionally occupied. The two pitches of its roof were supported by a row of bamboo poles, which running down the middle, divided the building into two parts. The sides of the roof were covered with thick double mats, and lined within with coarse Manchester cottons of various patterns."—"In the farther division of the building, a party of comedians was engaged in the midst of an historical drama, when we entered; but on our being seated, they broke off, and coming forward, made before us their obeisance of nine genuflexions and prostrations; after which they returned to their labours, keeping up an incessant noise and bustle during the day. The horrible crash of the gongs, kettle-drums, rattles, trumpets, and squalling flutes, were so stunning and oppressive, that nothing but the novelty of the scene could possibly have detained us for a moment. Their airs, rude and unpolished as they were, appeared to be regular compositions, and were sung in exactly measured time. One in particular attracted our attention, whose slow melancholy movement breathed that kind of plaintive softness so peculiar to the native airs of the Scotch, to which, indeed, it bore a very close resemblance. The voices of the women were shrill and warbling, but some of their cadences were not without melody. The instruments at each pause, gave a few short flourishes, till gradually overpowered by the swelling and deafening gong. By different gestures of the head, body, and arms, the dancers assumed a variety of figures; and all their motions were exactly adapted to the measure of the music."—"The Cochinchinese are very fond of theatrical amusements; the actors are busily engaged in their performances the whole day, proceeding apparently with as much ardour when there are few, or even no spectators present, as when there were many. Being hired for the day, a crowded or a thin audience makes but little difference to the performers; all their concern being the receipt of their pay on the finishing of their labour."—"Leaving the comedians in the midst of their labours, we walked across the village green, which was also the market-place, where we were highly entertained with a variety of sports and gambols. The fourth of June was for once a day of general festivity, in this part of Cochinchina. In one place we observed about a dozen of young fellows, playing at foot ball, with a bladder; in another, they were displaying their agility, by leaping over an horizontal pole; here a noisy groupe were amusing themselves in fighting cocks; there boys, in imitation of their elders, were training quails, and other small birds, and even grasshoppers, to tear one another in pieces; and in every corner gamesters were playing cards, or throwing dice. But that which most attracted our attention, was a party of young men keeping up a shuttle-cock in the air, by striking it with the soles of their feet. Nothing, indeed, could exceed the activity and energy of the men of Cochinchina. Active as they were in the use of their feet, their manual dexterity was not less remarkable. Jugglers, and conjurors, and posture-makers, were exercising their respective arts for the amusement of the crowd, and for their own advantage; and we found to our cost, that those who did not openly practise juggling as a profession, were equally expert in the art of picking pockets." P. 295, &c.

Arts and manufactures.

Their arts and manufactures are, as may be supposed, in their infancy, and do not appear to be in a state of progressive improvement. There is in this, and in all Oriental governments, a radical defect, which must ever operate against all national improvements; and that is, the want of a permanent security to property. In a country where the hand of arbitrary power can, at any time, dispossess a man of his property, what encouragement can he have to build an elegant house, to improve the cultivation of his land, to aim at perfection in any art, or, in short, to extend his ingenuity or industry, much beyond a supply of the mere necessaries of life. Their best houses are constructed of wood or bricks, which have been dried in the sun, are limited to one story, are thatched, and require constant attention to prevent them from mouldering into dust. On the low grounds, and in the neighbourhood of rivers, the houses are usually raised upon four posts of wood, or pillars of stone, to protect the inhabitants from vermin, and from inundations. Their city walls are but ill calculated for duration. The mass of loose earth heaped in the middle, has a constant tendency to push out the bricks or stones with which it is cased, so that the whole soon crumbles into a heap of ruins, and is buried under a rapid and vigorous vegetation. The houses in Turon, one of the sea-port towns, were, in general, clean and comfortable, and sufficiently compact to protect the inhabitants from the heat of the sun at one season, and the heavy rains at the other. Their household furniture is scanty, and rude in its construction. An earthen stove, an iron pot to boil their rice, which forms their chief article of food, a pan to fry their vegetables in oil, and a few porcelain cups and bowls, compose their domestic utensils. The floors of their houses are, indeed, covered with matting, ingeniously woven in different colours; but the art of making mats is so common among all the nations of the East, that the most beautiful are scarcely admired. Their vessels of cast iron are well executed, and equal in quality to those of the Chinese, but their earthen ware is far inferior. They work in metals with tolerable neatness; and as they are an acute and ingenious people, they might, under proper encouragement, make a rapid progress in the arts and manufactures.

Naval architecture.

The art in which they excel most, at present, is naval architecture, for which the size and quality of their timber is admirably fitted. Their row-gallies, built for pleasure, are very fine vessels; from 50 to 80 feet in length; and are sometimes composed of only five single planks, which extend from one extremity of the vessel to the other; the edges being morticed, kept tight by wooden pins, and bound firm by twisted fibres of bamboo, without ribs, or any kind of timbers. The company always sit in the forepart of the boat, and the servants and baggage occupy the stern; but as it would be deemed a breach of good manners in the rowers to turn their backs on the passengers, they stand with their faces towards the bow of the boat, and push the oars from them, instead of pulling towards them. Their foreign traders are built on the same plan as the Chinese junks, and are capable of carrying a great burden, but with more safety than speed. These vessels are divided into distinct compartments, by planks two inches thick, well caulked, and completely water tight; so that one ship may accommodate several merchants. A ship thus secured with cross bulk heads, may strike on a rock without sustaining any serious injury; and if a leak spring in one direction of the hold, it is not attended with any damage to the articles which fill the other.

Religion. The religion of the Cochinchinese, like that of almost all the Oriental nations, is a modification of the widely extended doctrine of *Buddha*, but apparently more simple, and less disguised with mysteries than that religion as practised in China. Their temples are, in general, very humble buildings, without the heavy curved roofs, or towering pagodas of the Chinese; but in many parts of the country there are monasteries amply endowed, of which the buildings are extensive, and enclosed with walls. These religious houses are supported by yearly contributions, levied by government, which, in the country, consist of the produce of the soil in kind; and, in the towns, of money, metals, clothing, and similar articles. From a pious sentiment of gratitude, they offer to the image of the protecting deity the firstlings of their flocks, and the first fruits of the earth; but, like other idolatrous nations, the Cochinchinese are extremely superstitious. When an infant dies, the parent endeavours to appease the offended deity by offerings of rice, oil, tea, money, or whatever he supposes may be acceptable. And, from the same principle of superstitious fear, large wooden stakes, or pillars, are erected in various parts of the country, for the purpose of marking the spot, where some public or private calamity may have happened, as the loss of a battle, the murder of an individual, or other calamity, and as a propitiation to the evil spirit, by whose influence it is supposed to have been produced.

Morals. The moral system of this country, as in China, is founded upon the precepts of Confucius; here, however, very little regard is paid to the external forms of morality. In that respect they are completely the reverse of their northern neighbours. Far from affecting the gravity and moroseness of the Chinese, they are gay and talkative, open and familiar; and the women are as gay and unreserved as the men. We have already remarked, that the female character is held in a state of complete degradation. The women are, indeed, considered as beings of an inferior nature to the men, by whom they are regarded as formed only to minister either to their wealth or their pleasure. Hence the morals of the females, married and unmarried, are extremely licentious; neither the husband, nor the father, having any scruples in abandoning the wife, or the daughter, to her gallant. In the married state, polygamy is not only tolerated, but unlimited by any law or rule; and here, as in China, the wife of the first marriage claims precedence, and takes the lead in all domestic concerns. The terms, on which the parties are united, are not more easy than those by which they are separated. The breaking of one of their copper coins, or a pair of chop-sticks, between husband and wife, before proper witnesses, is considered as the dissolution of their former compact, and the act of separation. These observations are not confined to the morals of the lower orders of the people: they apply not less forcibly to the first ranks in society, and to the officers of government; at least such is the general character of those resident in Turon and its environs, though the manners of a nation are not always to be estimated by what is found to prevail in the neighbourhood of a sea-port. It does not, however, appear that they have adopted from the Chinese, and other eastern nations, the inhuman practice of infanticide.

Language. The Cochinchinese have accurately preserved the written characters of the Chinese language, but the language which they speak is considerably different from theirs. But this is not surprising when we consider the various dialects which prevail in provinces of the same kingdom, and that the inhabitants of the northern and southern provinces of China are unintelligible to each other. People, however, who visit Cochinchina, find far less difficulty in making themselves intelligible than in China. While the morose and unbending Chinese will not condescend to employ the pencil to delineate objects, nor explain their meaning by signs or gestures, the accommodating Cochinchinese are ready to adopt any plan for the purpose of facilitating their intercourse with strangers.

History. Cochinchina was originally subject to the Chinese government; but having engaged in rebellion with the kingdom of Tung-quin, it became exposed to different usurpers, and both states were compelled to return to their former dependance about the 50th year of the Christian æra. The imperial authority, after its re-establishment, subsisted in Cochinchina till the year 263, when a powerful native, named Kulien, undertook to deliver his country from a foreign yoke. The descendants of that successful usurper enjoyed the throne of Cochinchina till 653; but with regard to the succeeding kings, the Chinese history is very defective.

In 1280, the king of Cochinchina, having heard of the revolution which had made the Mogul Tartars masters of all China, sent to the new emperor deputies loaded with presents, in order to pay him homage. The deputies were honourably received; but the Emperor, not content with tribute, carried his pretensions farther, and attempted to seize the government of the country. This occasioned another war with the Chinese, in which the kings of Cochinchina maintained their independence by paying the usual tribute to the emperor.

The Mogul Tartars having been expelled from China, the new emperor, upon his accession to the throne, sent a friendly deputation to the king of Cochinchina, and the latter sent his tribute to the new monarch. In 1373 the king of Cochinchina carried fire and sword into Tung-quin; and a long and bloody war betwixt these two monarchs ensued, which was not terminated till the year 1471, when, after a desperate battle, the king of Tung-quin became absolute master of Cochinchina. It, however, again recovered its independence, and continued afterwards to be governed by its own kings. Excepting one attempt made by the Tung-quinese to subjugate this country in 1671, in which they were unsuccessful, they have remained peaceably within their own boundaries, while Cochinchina has subdued the mountaineers, and even the kings of Tsiampa, and Camboya, whom she has compelled to pay tribute. From that period, till the year 1774, little or nothing is known of the history of that country; but, from the information of a Monsieur Barissy, a French officer who commanded a frigate in the service of his Cochinchinese majesty, Mr Barrow has been enabled to lay before the public a very curious and interesting sketch of its recent revolutions, and its present political state, of which the following is an abstract.

In the year 1774 an insurrection commenced, headed by three brothers, Yin-yac a merchant, Long-niang a general officer, and the third a priest, whose name is unknown, by which Caung-shung was deprived of the throne of Cochinchina, and he, and as many of his family as fell into the hands of the rebel party, were put to death. The kingdom was then divided among the three, and Long-niang soon made war on the king of Tung-quin, a vassal of China, and obliged him to flee to Pekin for the purpose of demanding assistance. Kien-long, the emperor, ordered his *invincible* army, under the Viceroy of Canton, to march and reinstate the king of Tung-quin; but the politic Long-niang, (who had assumed the title of Quang-tung,) laid waste the country, and soon obliged them to retreat from want of provisions, the army of his opponent having lost, by famine and the sword, nearly 50,000 men. The Viceroy Foo-chang-tong was obliged to negotiate, but his antagonist refused to yield the title to the kingdom of Tung-quin. Foo-chang-tong, more fitted for the cabinet than the field, resolved to employ finesse, and he represented to the emperor that his invincible army had performed most wonderful feats, but that the supposed usurper was much beloved by the Tung-quinese, and had a fair title to the abdicated throne; and that it would be politic to invite him to the court of Pekin, to perform the accustomed ceremonies and duties of vassalage. Instead of making his personal appearance, however, the wary Long-niang imposed upon the court of Pekin one of his generals, as his representative. The mock king was favourably received, and sent back: but Long-niang, puzzled by this unexpected issue, rewarded the faithful service of his representative by putting him and the whole of his suite to death, in order to prevent a discovery of the deception.

At the time of the insurrection, a French missionary, named Adran, resided at the court of Cochinchina, as tutor to the son of the king, and from the general wreck and slaughter he rescued the queen, and the prince, with the princess, and their infant son. Their first concealment was in a wood, under the branches of a *royal* banyan tree; and after the ardour of search had subsided, the fugitives proceeded to Sai-gong, where the prince was crowned as king, under the name of Caung-shung. A large army, however, sent by Yin-yac the *merchant king*, compelled the royal family again to flee, and they embarked on the river of Sai-gong, and landed in a small uninhabited island in the gulf of Siam. There the king was joined by about 1200 of his adherents; but the usurper preparing an expedition against him, Caung-shung resolved to throw himself on the protection of the king of Siam. This monarch granted an asylum to the exiled prince; and, being at war with the Birmans, he accepted of his proffered assistance, which, by the aid of the European tactics taught to Caung-shung to Adran, was so effectual, that, in a short time, the Birmans were compelled to sue for peace. Jealousy of his talents, however, and suspicion of ambitious views, raised in Siam a party against poor Caung-shung; and he was obliged, at the head of his faithful followers in arms, to force his way out of the capital of Siam, to re-embark on some Siamese vessels and Malay proas seized in the harbour, and again to occupy his old island; which, with the guns taken from the vessels, he fortified in such a manner as to be equally secure against the king of Siam and his own rebellious subjects.

While these events were passing, Adran had visited the southern provinces of Cochinchina, and finding the sentiments of the people hostile to the usurper, he resolved to sail for France, and to apply to its court for effectual assistance in reinstating the king on his throne. He took with him from Pondicherry the son of Caung-shung, and arrived at Paris in 1787. His project was presented and adopted; and, in the course of a few months, a treaty was signed at Versailles between Louis XVI. and the ambassador of the king of Cochinchina, a full copy of which is given by Mr Barrow. In that treaty, it is stipulated among other things, that France shall immediately furnish to her ally a fleet of 20 ships of war, with five regiments of French, and two of colonial forces, to be under the absolute command of the king of Cochinchina; and shall also immediately advance one million of dollars, half in specie, and the other in arms and ammunition. In return, the king of Cochinchina ceded, in perpetuity to France, the bay and peninsula of Turon, with the adjacent islands; stipulated to furnish 14 ships of the line, with stores and tackling; to admit an establishment of officers of the marine in his dominions; and to allow the French consuls to build any number of vessels in his ports; and, for that purpose, to fell any quantity of timber in his forests. And in the event of the king of France being at war with any power in India, he is permitted to raise and discipline in the European manner 14,000 Cochinchinese soldiers; and the king is to provide 60,000 more, disciplined in the manner of their country.

It is unnecessary to point out the policy of the court of France in framing that treaty, which, happily for the interests of the British East India settlements, was frustrated, partly by the influence of the mistress of Conway, the governor of Pondicherry, but principally by the event of the French revolution. Adran, created bishop by the court of France, and appointed plenipotentiary, proceeded to Pondicherry, and although he was then crossed in his purposes by the intrigues of Madame de Vienne, as already mentioned, yet he did not desist from his grand design of reinstating Caung-shung on the throne. With the young prince he proceeded to the coast of Cochinchina, where he learned that the king, after a miserable subsistence of two years on the island, had been induced, by the circumstance of the two usurpers contending with each other, to land in his kingdom; that the people had risen in his support; and that the royal party had proceeded to Sai-gong, the works of which they had put into a good state of defence. There they were joined in 1790 by bishop Adran, and measures were taken during that year, for equipping an army and a fleet.

In 1791, the rebel Long-niang, alias Quang-tung, died, and Caung-shung immediately commenced his operations, by surprising, attacking, and destroying the fleet of Yin-yac, the *merchant king*; and in 1793, the southern part of the kingdom had submitted to the lawful sovereign. Yin-yac did not long survive the destruction of his fleet, for he died that same year. His son succeeded, and was dispossessed of his capital in 1796. Against the son of the other usurper, who kept possession of the kingdom of Tung-quin, this *Gustavus* of Cochinchina was preparing an armament in 1800. "Although no authentic accounts since that period have reached Britain, there is good reason to believe, that he has reconquered the whole of that country."

From what Caung-shung has atchieved, it must be acknowledged that he is a great and extraordinary man. By the aid of an education, which may be called European, he has risen superior to those around him; and his superiority does not consist merely in patience, in fortitude under suffering, or in the achievement of victory, but by civil regulations, and by the introduction of arts, he has done much to civilize his country: the industry, ingenuity, and energy of his people are excited, and probably they will soon be enabled to assume a more elevated rank among the nations of Asia. During the short intervals of peace which he has been permitted to enjoy, he has laboured, by the wisest institutions, to promote the peaceful as well as the warlike arts among his subjects. He has encouraged agriculture and manufactures of every denomination; he has established public schools in every part of his dominions; he has caused a regular survey to be made of the whole sea-coast, and buoys and land marks to be erected in the dangerous places; he has opened mines, and erected smelting furnaces. With a view to the military improvement of his country, he employed the faithful Adran to translate into the Chinese language, a system of European tactics for the regulation of his army; and applied himself to the erection of a marine with such indefatigable activity, that, in 1800, he had actually a fleet of no less than 1200 vessels, several of them of European construction, and the whole trained to manœuvre by signals, according to the most approved methods of modern times. He is very desirous to have the assistance of European officers, and men of science, in the different departments of his government; and has himself no mean knowledge of many of our useful arts. To shipbuilding in particular, he has applied himself with such persevering industry, that he is said to have purchased a Portuguese vessel, for the express purpose of taking it in pieces, plank by plank, with his own hands, fitting in a new piece of similar form and dimensions, till the whole had been completely renovated. While he pays a scrupulous regard to the maxims of Confucius, he openly declares his great veneration for the doctrines of Christianity, and tolerates it and all other religions.

The following is Mr Barrow's account of the daily life of this extraordinary personage, who in 1807 was in the 51st year of his age. "To enable him the better to attend to the concerns of his government, his mode of life is regulated by a fixed plan. At six in the morning he rises from his couch, and goes into the cold bath. At seven he has his levee of mandarins: all the letters are read which have been received in the course of the preceding day, of which his orders are minuted by the respective secretaries. He then proceeds to the naval arsenal, examines the works that have been performed in his absence, rows in his barge round the harbour, inspecting his ships of war. He pays particular attention to the ordnance department; and in the foundery, which is erected within the arsenal, cannon are cast of all dimensions. About twelve or one he takes his breakfast in the dock-yard, which consists of a little boiled rice and dried fish. At two he retires to his apartment and sleeps till five, when he again rises, gives audience to the naval and military officers, the heads of tribunals, or public departments, and approves, rejects, or amends whatever they may have to propose. These affairs of state generally employ his attention till midnight, after which he retires to his private apartments, to make such notes and memorandums as the occurrences of the day may have suggested. He then takes a light supper, passes an hour with his family, and between two and three in the morning retires to his bed; taking in this manner at two intervals, about six hours of rest in the four-and-twenty."

His forces, as stated by captain Barissy, were in the year 1800 as follows:

Army.		*Men.*
24 squadrons of buffalo cavalry		6,000
16 battalions of elephants (200 beasts)		8,000
30 battalions of artillery		15,000
		29,000
Brought forward		29,000
25 regiments of 1200, each trained in the European manner		80,000
Infantry with matchlocks, sabres, &c. trained in the ancient manner of the country		42 000
Guards regularly trained in European tactics		12,000
Land forces		113,000
Marine.		
Artificers in the naval arsenal	8000	
Sailors registered and borne on the ships in the harbour	8000	
Attached to the European built vessels	1200	
Attached to the junks	1600	
Attached to the 100 row galleys	8000	26,800
Total		139,800

Money.

The Japanese is the only current money in Cochinchina, and is paid and received by weight. The money of the country is of copper, as large as our common counters, of a round figure, and has a hole in the middle, by which it may be strung in the same manner as beads.

Commercia advantage

Cochinchina is extremely well situated for commerce. It lies in the direct line of our navigation to China, and in the immediate vicinity of the islands in the Indian Archipelago; and the commodious harbours formed on its coasts, particularly at Turon, afford a safe retreat for ships of any burden in the most tempestuous seasons. It furnishes many articles of great value in the Chinese market, and might open a ready market for many of our manufactures. Besides a variety of valuable scented woods, its forests contain an inexhaustible store of teak, and other timber for ship-building, of which our supply in other eastern countries is said to be both scanty and precarious; and its fertile vallies yield abundance of rice, sugar, pepper, silk, cotton, and other vegetable productions. Among the articles of luxury, which are at all times in demand by the Chinese, may be enumerated the areca nut, cardamoms, ginger, and other spices; the nests already described; the Bichos du Mar, or sea slugs, in commercial language called *trepan;* the fins of sharks; and many marine productions of a gelatinous quality, both animals and vegetables. A rich gold mine has, it is said, been opened near Hué, the northern capital, and gold dust has been brought at different periods from the mountains. Silver mines also have been discovered, and the silver is now brought to market in bars about five inches long, and in value about eleven Spanish dollars. These articles, so valuable in China, might be taken by us in exchange for our various manufactures in iron and steel; our woollens, cottons, and muslins; our naval stores; our opium, and other drugs; all of which have at various times been disposed of in Cochinchina at an advance of 30 per cent. and their value paid in ingots of silver. By a trade of that kind, were there a British factory established at Turon, as much specie might be saved to Great Britain, or to our settlements in India, as the value of the commodities might amount to in China; and if the Chinese government shall ever carry into effect a threatening which they have often held out, of excluding foreign traders altogether from their ports, our trade might still be carried on, and perhaps with greater advantage, by means of Chinese junks bringing cargoes of tea and silks and other articles to Cochinchina, and thus avoiding the exorbitant duties levied at Canton on foreign vessels. In this manner too, an advantageous trade might be opened up to the numerous islands which lie scattered in the Indian and Chinese seas, some of which have of late years been wrested from the hands of our enemies; and the Siamese and Cambodians, and other neighbouring nations on the continent, might be induced to bring the produce of their respective countries to Cochinchina, and barter it with us for such articles as they want. Mr Barrow is of opinion, from what he observed of the disposition of the people at Turon, that neither the king of Cochinchina, nor the natives, would be averse to an intimate connection with the British, provided suitable overtures were made to them in a direct manner by *the British government itself*, and not through any *commercial body*, to whom, like the Chinese, they pay no respect. And as their trade with China, which formerly employed upwards of two hundred of their largest vessels, has been wholly suspended since the rebellion in the country, he believes that it would not be difficult for Britain, the greatest maritime and commercial power in the world, by prudent management, to establish an intercourse so obviously beneficial to both countries. The thoughts which he suggests upon that subject deserve attention.

See Barrow's *Voyage to Cochinchina.* Grosier's *Description of China*, vol. i. p. 300. *Exposé Statistique du Tonkin de la Cochinchine du Camboge*, &c. tom. ii. p. 1. *Annales des Voyages*, par M. Malte Brun, tom. iii. (A. P.)

COCHINEAL, the name of a valuable scarlet dye obtained from an insect, the Coccus *Cacti* of naturalists, which is found on the *Cactus opuntia*, or prickly pear tree called *Nopal*, or *Nopallica*, by the Indians. As the natural history of the insect itself will be given under the article ENTOMOLOGY, and the method of using the dye which is obtained from it under the article DYEING, we shall confine ourselves at present to such economical details as do not belong to either of these articles.

The *Cactus opuntia*, or *Nopal*, on which the insects are reared, is generally planted by the Indians near their habitations, in an argillaceous earth mixed with gravel and stones. In holes about half a yard deep, and about two yards distant from each other, one or two leaves of the nopal are placed in a flat position, and then covered with earth. These leaves grow up into a single stem, which divides into branches that successively produce fresh leaves. The stem and the branches are full of knots, from which the leaves grow. The plant is usually about three yards in height. The decayed branches are carefully removed, and the plants are kept free of all kinds of weeds. A collection of these trees forms a *Nopalerie.* The female cochineal insects are placed, about the 15th of October, in a number of small nests among the leaves of the nopal, and they immediately wander over the plant in quest of the particular branches to which they attach themselves, and during the time of breeding they are preserved with the utmost care from violent winds, frosts, &c. and from the depredations of particular birds and worms. After attaining their full growth, they are put into earthen pots, and when they have been confined for some time, they are killed and put into bags.

The following curious details respecting cochineal are abridged from the writings of Humboldt, which contain not only the most recent, but the most correct account of this singular insect that has yet been published.

The rearing of the cochineal, (*Grana Nochiztli*,) is of great antiquity in New Spain; and it is probable that it goes beyond the incursions of the Toltec tribes. In the time of the dynasty of Aztec kings, the cochineal was more general than at present. There were nopaleries not only in Mixtecapan (la Misteca), and in the province of Huaxyacac (Oaxaca), but also in the intendancy of Puebla, in the environs of Cholula and Huejotzingo. The vexations to which the natives were exposed in the beginning of the conquest, and the low price at which the encomenderos forced the cultivators to sell the cochineal, occasioned this branch of Indian industry to be everywhere neglected, excepting in the intendancy of Oaxaca. It is scarcely 40 years since the peninsula of Yucatan still possessed considerable nopaleries. In a single night, all the nopals, on which the cochineal lives, were cut down. The Indians pretend that the government took this violent resolution to raise the value of a commodity, of which they wished to secure the exclusive property to the inhabitants of Misteca. On the other hand, the whites maintain that the natives, irritated and discontented with the price fixed by the merchants on the cochineal, came to a general understanding, to destroy at once, both the insect and the nopals.

The quantity of cochineal which the intendancy of Oaxaca furnishes to Europe, may be estimated in common years, including the three sorts, *grana*, *granilla*, and *polvos de grana*, at 4000 *zurrones*, or 32,000 *arrobas*, which, calculating the arroba at 75 double piastres, amounts to 2,400,000 piastres. The cochineal exported from Vera Cruz, was

In 1802.	Arrobas.	Value in Double Piastres.
Grana Fina, ...	43,277	3,303,470
Granilla, ...	2,355	50,472
Polvos de Grana, . .	1,322	14,615
Total, ...	46,954	3,368,557

In 1803.	Arrobas.	Value in Double Piastres.
Grana Fina, ...	27,251	2,191,399
Granilla, ...	1,573	40,226
Polvos de Grana, . . .	786	7,048
Total, ...	29,610	2,238,673

But since the produce of one harvest is often augmented by a portion of the produce of the preceding year, the progress of cultivation cannot be determined from the quantity exported. The nopaleries in general increase very slowly in Misteca. In the intendancy of Guadalaxara, scarcely 800 arrobas of cochineal are produced annually. Raynal estimates the whole exportation of New Spain at 4000 quintals, an estimate too low by one half. The East Indies have only begun to pour their cochineal into commerce; but the quantity is very inconsiderable. Captain Nelson carried off the insect from Rio Janeiro* in 1793, and nopaleries have been established in the environs of Calcutta, Chittagong, and Madras. Much difficulty was experienced in procuring the species of cactus proper for the nourishment of the insect. We do not know if this Brasilian cochineal transported to Asia, be the mealy species of Oaxaca, or if it be the cotton cochineal (*grana silvestre*).

Humboldt had occasion to observe the wild cochineal in the kingdom of New Granada, Quito, Peru, and in Mexico, though he was not fortunate enough to see the fine cochineal; but having consulted persons who had lived long in the mountains of Misteca, and having had at command extracts from several manuscript memoirs, drawn up by order of the Count de Tessa, during his stay at Mexico, by alcaides and ecclesiastics of the bishopric of Oaxaca, he obtained some useful information respecting an insect which has become of the very first importance to European manufactures.

---

* This cochineal is the *Grana silvestre.* It was first cultivated at Rio Janeiro in 1770, by M. Henriquez de Payra, who has written a detached history of it, with many plates, the MS. of which is in the archives of the Academy of Lisbon.

The fine cochineal differs from the wild one, not only in size, but also in being mealy and covered with a white powder, while the wild one is enveloped in a thick cotton, which prevents its rings from being distinguished; but the metamorphoses of the two insects are the same. In those parts of South America where for ages the wild cochineal has been reared, it has never yet lost its down. It is true, that in the nopaleries established by M. Thiery at St Domingo, it was thought to be observed, that the insect under the care of man increased in size, and underwent a sensible change in the thickness of its cotton covering; but M. Latreille, who is inclined to look upon the wild cochineal as a different species from the fine one, believes that this diminution of down is merely apparent, and that it must be attributed to the thickness of the body of the insect. The rings on the back of the female being more dilated, the hairs covering this part must appear less close, and consequently clearer. Humboldt was informed by several persons who had long lived in the neighbourhood of Oaxaca, that sometimes among the small *coccus* recently brought into the world, individuals are observed covered with very long hair. But it must not be forgotten, that the fine cochineal, on leaving the body of the mother, is wrinkled in the back, and covered with twelve silks frequently very long, which disappear when it becomes adult. Those who have not attentively compared the offspring of the fine cochineal, with that of the wild cochineal, are naturally struck with the presence of these hairs. The fine cochineal appears powdery ten days after its birth, when it frees itself from its fringy dress of small silks, whereas the wild cochineal is more and more covered as it gets older, its down thickens, and the insect resembles a small white flake, at the period which precedes the conjunction of the two sexes.

It is sometimes observed in the nopaleries of Oaxaca, that the winged male of the fine cochineal couples with the female of the wild cochineal. This fact has been cited as an evident proof of the identity of the species; but we commonly see in Europe *coccinelles* couple together essentially different in their form, shape, and colour. When two species of insects are in the same vicinity, we ought not to be astonished at their coupling together.

M. Thiery thought himself warranted in maintaining, that the fine cochineal and the plant on which it feeds, are both found wild in Mexico, and that the insect and the nopal of the plantations of Oaxaca, have been insensibly modified in their form by means of long culture. This supposition, however, appears equally gratuitous with that which would pronounce grain, maize, and the banana, to be degenerated plants. The coccus cacti has an infinite number of enemies among the insects and birds. Wherever the cotton cochineal propagates of itself, it is not to be found in any abundance, from which we may easily conceive that the mealy cochineal must have been still more rare in its native country, because it is much more delicate, and not being covered with down, is more sensible to the cold and humidity of the air. In discussing the question, whether the fine cochineal would propagate without the care of man, the subdelegate of the province of Oaxaca, Ruiz de Montaya, (*Gazeta de Literatura de Mexico*, 1794, p. 228.) cites a very remarkable fact in his memoir, "that at seven leagues distance from the village of Nexapa, there is a place where, favoured by particular circumstances, the most beautiful *grana fina* is to be found, on very high and very prickly wild nopals, without any pains having ever been bestowed in cleaning the plants, or in renewing the offspring of the cochineal." Besides, we are not to be astonished, that even in a country where this animal is indigenous, it should seldom be found in a wild state, from the time that it began to be in request among the inhabitants, and to be reared in nopaleries. It is probable that the Toltecs, before undertaking so troublesome a species of cultivation, collected the fine cochineal on the nopals, which grew spontaneously on the sides of the mountains of Oaxaca. Gathering the females before laying, the species would soon be destroyed; and to obviate this progressive destruction, and prevent the mixture of the cotton and mealy cochineals on the same cactus, (the former depriving the latter of all nourishment,) nopaleries were established by the natives.

The plants on which the two species of cochineal are propagated, are essentially different; and this undoubted fact is one of those which indicate a primitive difference between the *grana fina*, and the *grana silvestre*. Is it probable if the mealy cochineal were merely a variety of the cotton cochineal, that it would perish on the same cactus which nourishes the latter, and which botanists designate by the names of *Cactus opuntia*, *Cactus tuna*, and *Cactus ficus indica*? M. Thiery asserts, that in the plain of Cul-de Sac in St Domingo, the cotton-cochineal does not live on the *Cactus tuna*, but on the *Cactus pereskia*, which he classes among the articulated Indian figs; and Humboldt believes that this naturalist has confounded a variety of opuntia, with the true pereskia, which is a tree with large and thick leaves, and on which he never yet found any cochineal. He considers it also as extremely doubtful, whether the plant called by Linnæus *Cactus coccinellifer*, cultivated in Europe, is the nopal on which the Indians of Oaxaca rear the mealy cochineal. M. Decandolle, (*Plantes grasses de M. M. Redouté et Decandolle*, livraison 24.) appears to be of Humboldt's opinion; for he cites the wild nopal of Thiery de Menouville, as synonymous with the cochineal Indian fig, which is entirely different from that of the plantations. Linnæus indeed gave the name of *Cactus coccinellifer* to the Indian fig, with which several botanical gardens of Europe had received the cotton cochineal, a species with a purple flower, (*Ficus Indica vermiculos proferens* of Plukenet,) which grows wild in Jamaica, the island of Cuba, and in almost all the Spanish continental colonies. Humboldt shewed this cactus to well-informed persons, who had carefully examined the nopaleries of Oaxaca, and they uniformly told him, that the nopal of the plantations is essentially different from it, and that the latter is never to be found in a wild state. The Abbé Clavigero, also, who lived five years in Misteca, expressly says, that the fruit of the nopal on which the fine cochineal is reared, is small, insipid, and white, while the fruit of the *Cactus coccinellifer* is red. Ulloa maintains that the true nopal is without prickles; but he appears to have confounded this plant with an Indian fig, which is found in the gardens (*conucos*) of the Indians of Mexico and Peru, and which the creoles, on account of its gigantic size, the excellence of its fruits, and the beauty of its articulations, which are of a bluish green, and destitute of prickles, designate by the name of *Tuna de Castilla.* This nopal, the most elegant of all the opuntia, is in fact fit for the nourishment of the mealy cochineal, especially after its birth; but it is seldom to be found in the nopaleries of Oaxaca.

In the intendancy of Oaxaca, the Indians do not all follow the same method in rearing the cochineal, which M. Thiery de Menouville saw practised in his rapid passage through San Juan del Re, San Antonio, and Quicatlan. The Indians of the district of Sola and Zimatlan establish their nopaleries on the slope of mountains, or in ravines, two or three leagues distant from their villages. They plant the nopals, after cutting and burning the trees which covered the ground. If they continue to clean the ground twice a year, the young plants are able to maintain the cochineal in the third year. For this purpose, the proprietor of a nopalery purchases, in the months of April or May, branches or joints of the *Tuna de Castilla*, laden with small cochineals, (*semilla*) recently hatched. These branches, destitute of roots, and separated from the trunks, preserve their juice for several months. They are sold for about three francs the hundred in the market of Oaxaca. The Indians preserve the semilla of the cochineal for twenty days in caverns, or in the interior of their huts, and after this period they expose the young coccus to the open air. The branches to which the insect is attached, are suspended under a shed covered with a straw roof. The growth of the cochineal is so rapid, that even in the months of August and September, we find mothers already big before the young are yet hatched. These mother cochineals are placed in nests, made of a species of tillandsia, called *paxtle*. They are carried in these nests two or three leagues from the village, and distributed in the nopaleries, where the young plants receive the semilla. The laying of the mother-cochineal lasts from thirteen to fifteen days. If the situation of the plantation is not very elevated, the first harvest may be expected in less than four months. It is observed, that in a climate more cold than temperate, the colour of the cochineal is equally beautiful, but that the harvest is much later. In the plain, the mother cochineals grow to a greater size, but they meet with more enemies in the innumerable quantity of insects, (*xicaritas, perritos, aradores, agujas, armadillos, culebritas,*) lizards, rats, and birds, by which they are devoured. Much care is necessary in cleaning the branches of the nopals. The Indian women make use of a squirrel or stag's tail for that purpose; they squat down for hours together beside one plant; and notwithstanding the excessive price of the cochineal, it is to be doubted if this cultivation would be profitable, in countries where the time and labour of man might be turned to account. At Sola, where very cold rains occasionally fall, and where it even frequently freezes in the month of January, the natives preserve the young cochineals by covering the nopals with rush mats. The price of the semilla of *grana fina*, which generally does not amount to more than five francs per pound, frequently rises there to 18 and 20.

In several districts of the province of Oaxaca, they have three cochineal harvests in the year, of which the first (that which gives the semilla) is not lucrative, because the mother preserves for a very short time the colouring juice, if she dies naturally after having laid. This first harvest furnishes the *grana de pastle*, or nest cochineal, so called because the mothers after laying are found in the same nests which have been suspended to the nopals. Near the town of Oaxaca, the cochineal is sown in the month of August; but in the districts of Chontale, this operation does not take place till the month of October; and on the coldest table lands not even till the months of November and December.

The cotton or wild cochineal which gets into the nopaleries, and the male of which, according to the observation of Mr Alzate, is not much smaller than the male of the mealy or fine cochineal, does much injury to the nopals; and accordingly the Indians kill it wherever they find it, though the colour which it yields is very solid and very beautiful. It appears that not only the fruits, but also the green branches of several species of cactus, will dye cotton violet and red, and that the colour of the cochineal is not entirely owing to a process of animalization of the vegetable juices in the body of the insect.

At Nexapa, they reckon that in good years, one pound of semilla of mealy cochineal placed on nopals in the month of October, in the month of January yields a harvest of 12 pounds of mother-cochineals, leaving sufficient semilla on the plant, that is to say, beginning the harvest only when the mothers have already produced the half of their young. This new semilla again produces till the month of May 36 pounds. At Zimatlan and other villages of Misteca and Xicayan, they scarcely reap more than three or four times the quantity of cochineal sown. If the south wind, which is very pernicious to the growth of the insect, has not blown long, and the cochineal is not mixed with *tlasole*, that is to say, with the spoils of the winged males, it loses only two-thirds of its weight when dried in the sun.

The fine and the wild kinds of cochineal appear to contain more of the colouring principle in temperate climates, especially in regions where the mean temperature of the air is 64° and 68° of Fahrenheit. Humboldt found the wild cochineal in abundance in the most opposite climates, in the mountains of Riobamba, at 9513 feet English of absolute elevation, and in the plains of the province of Jaen de Bracomaros, under a burning sky, between the villages of Tomependa and Chamaya.

Around the town of Oaxaca, and especially near Ocotlan, there are plantations (*haciendas*) which contain from 50 to 60,000, planted in lines like pites or *magueys de pulque*. The greatest part of the cochineal which is employed in commerce is, however, produced in small nopaleries belonging to Indians of extreme poverty. The nopal is seldom allowed to grow higher than 47 inches, in order that it may be the more easily cleared of the insects which devour the cochineal. The varieties of the cactus which are roughest and most prickly are even preferred, because these arms serve to protect the cochineal from flying insects; and the flower and fruit are carefully cut, to prevent these insects from depositing their eggs in them.

The Indians who cultivate the cochineal, and who go by the name of *Nopaleros*, especially those who live round the town of Oaxaca, follow a very ancient and a very extraordinary practice, that of *making the cochineal travel*. In that part of the torrid zone, it rains in the plains and vallies from May to October, while in the chain of neighbouring mountains called Sierra de Istepeje, the rains are only frequent from December to April. In place of preserving the insect in the rainy season in the interior of their huts, the Indians place the mother-cochineals, covered with palm leaves, by beds, in baskets made of very flexible claspers. These baskets (*canastos*) are carried by the Indians on their backs as quickly as possible to the mountains of Istepeje, above the village of Santa Catalina, at nine leagues distance from Oaxaca. The mother-cochineals produce their young by the way. On opening the canastos, they are found full of young coccus, which are distributed on the nopals of the sierra. They remain there till the month of October, when the rains cease in the lower regions. The Indians then return to the mountains in quest of the cochineal, for the purpose of replacing it in the nopaleries of Oaxaca. The Mexican in this way withdraws the insects from the pernicious effects of the humidity, in the same manner as the Spaniard travels with his merinos from the cold.

At the time of the harvests, the Indians kill the mother cochineals, which are collected on a wooden plate called *chilcalpetl*, by throwing them into boiling water, or heaping them up by beds in the sun, or placing them on mats in the same ovens of a circular form (*temazcalli*), which are used for vapour and hot air baths. The last of these methods, which is least in use, preserves the whitish powder on the body of the insect, which raises its price at Vera Cruz and Cadiz. Purchasers prefer the white cochineal, because it is less subject to be fraudulently mixed with parcels of gum, wood, maize, and red earth. There exist in Mexico very ancient laws (of the years 1592 and 1594) for the prevention of the falsification of cochineal. Since 1760, they have even been under the necessity of establishing in the town of Oaxaca, a jury of *veadores*, who examine the bags (*zurrones*) previous to their being sent out of the province. They order the cochineal exposed to sale to have the grain separated, that the Indians may not introduce extraneous matter in those agglutinated masses called *bodoques*. But all these means are insufficient to prevent fraud. However, that which is practised in Mexico by the *tiangueros* or *zanganos* (*falcificadores*) is inconsiderable in comparison of that which is practised on this commodity in the ports of the Peninsula, and in the rest of Europe.

The following is a statement of the quantity of cochineal exported at different times.

Quantity of cochineal exported from New Spain by Vera Cruz in 1787, 1788, 1789, *and* 1790.

	Arrobas.	Value in Double Piastres.
First quality, ...	91,346	7,764,469
Second quality, ...	7,973	159,470

Quantity of cochineal exported in the Fleet commanded by Ulloa in 1778.

	Arrobas.	Value in Double Piastres.
First quality, ...	26,400	2,243,203
Second quality, ...	1,052	21,049
In dust, 14 pieces, . .		222

Cochineal exported from Vera Cruz annually, on an average of seven years of peace.

Grana, Granilla, and Polvos de Grana, 4000 zurrones.
Valued at . . . . £504,000 sterling.

See Humboldt's *Political Essay on the Kingdom of New Spain*, vol. iii. and iv. Ulloa's *Voyage to South America*, vol. i. p. 325. Lond. 1807. See also Dyeing and Entomology. (π)

COCHLEARIA, a genus of plants of the class Tetradynamia, and order Siliculosa. See Botany, p. 260.

COCK. See Ornithology.

COCKERMOUTH, a town of England, in the county of Cumberland, is situated a little above the confluence of the river Cocker with the river Derwent. The Cocker separates the upper from the lower parts of the town, which are united by a bridge of one arch. Although the town is irregular, it contains many modern and well built houses. The street which leads to the castle is very steep, and contains several excellent buildings. The street which leads to Derwent bridge, is spacious and elegant, and many of the houses are handsomely built with red freestone. The market house, moot hall, and shambles, are gloomy and inconveniently situated; and the church, which is spacious, was, with the exception of the old tower, rebuilt of freestone, in 1711. The ruins of the castle, which was built soon after the conquest, stood on the top of an artificial mound, raised as a precipice on the banks of the Derwent. The circuit of the wall is about 600 yards, and it appears to have been of a quadrangular form, and guarded by square towers. It commands a beautiful and extensive prospect. There is a public walk, a mile long, on an extensive plain, beneath the Derwent; one end of this walk is terminated by scattered rocks covered with trees, and the other by the ruins of the castle. The principal articles of manufacture here are tanned leather, hats, shalloons, common woollen cloths, checks, and coarse linens.

Inhabited houses in 1811, ...	602
Families that occupy them, ...	709
Families employed in trade, &c.	386
Number of males, ...	1342
Number of females, ...	1622
Total population, ...	2964

COFFEE, is the name given to a liquor, made by a decoction, or an infusion of the seeds of the coffee berry after they have undergone torrefaction, and have been ground to powder.

In treating this subject, we shall first direct the reader's attention to the history of coffee; secondly, to the method of cultivating the coffee plant; thirdly, to the best modes of using it; and, lastly, to a few commercial details of a general nature.

On the History of Coffee.

History of coffee.

The coffee plant does not appear to have been known to the Greeks or Romans, nor are there any facts on which we can rely, respecting its origin in the East. In a manuscript now deposited in the Bibliotheque Nationale, coffee is said to have been introduced into Arabia about the middle of the 15th century, by Megaleddin, Mufti of Ada, who met with it during a journey in Persia. From Ada the use of coffee rapidly extended to Mecca, Medina, and other Arabian towns, and in a short time public coffee houses were every where established in Persia. At Grand Cairo, where it was speedily introduced, the use of it was prohibited in 1511, on the supposition that it produced intoxication, and excited improper feelings. This prohibition, however, was soon removed; but in 1523, when a second attempt was made to prohibit its use, a violent commotion took place in the city, and coffee was ever afterwards drunk with impunity.

A similar opposition was made to the use of coffee in Constantinople. Coal being one of the substances prohibited by Mahomet as unfit for human food, the dervises pretended that roasted coffee must be included in this prohibition, and with the aid of the Mufti, who held the same opinion, all the coffee houses were shut up. Upon the accession of a more liberal Mufti, the coffee houses were again opened; but it was found soon afterwards, that these places of resort were the haunts of the vicious and disaffected, and upon this new plea they were again shut up.

The use of coffee, as a beverage, in the west of Europe, appears to have been known about the end of the 16th century. It was introduced into Marseilles, in 1644, by some gentlemen who accompanied Monsieur De la Haye to Constantinople. Several bales were brought from Egypt to Marseilles, in 1660, and in 1671 a coffee house was opened in that city. Thevenot had already brought a small quantity of it to Paris, in 1657; but it was not generally introduced into that metropolis till 1669, by the ambassador from the Porte; and in 1672, a public coffee house was opened by one Pascal, an Armenian, who afterwards went to London.

Nearly about the same time, coffee was introduced into London. So early as 1652, Danial Edwards, a Turkish merchant, brought with him a Greek servant, who understood the method of roasting and preparing it, and who was the first who sold coffee publicly. In the year 1660, a duty of four pence was laid upon every gallon of coffee; and in 1663 it was enacted, that all coffee houses should take out a licence at the quarter sessions.

We are informed by Boerhaave, in his "Index to the Leyden Garden," that Nicolas Witsen, governor of the Dutch East India Company, instructed Van Hoorn, governor of Batavia, to procure the coffee plant from Mocha, and to cultivate it at Batavia; and that this was accomplished in 1690. Many plants are said to have been raised at that settlement, one of which was sent to Amsterdam, where it bore fruit. From Amsterdam a fine plant was sent to Louis XIV. in 1714, which is said to have been the parent of all that have since been cultivated in the Dutch and the French West India islands. The introduction of the coffee plant into Java is placed much later by Stavorinus, who asserts, that it was first introduced from Mocha into Batavia, in 1722, or 1723, by M. Zwardekrom, the governor general. In 1717, several coffee plants were sent to Martinique. In 1718, they were introduced from Arabia into the Isle of Bourbon, and in the same year into Cayenne, and in 1732 it was cultivated in Jamaica.

In the year 1784, the cultivation of coffee was introduced into the Spanish possessions in eastern Terra Firma, by D. Barthelemy Blandin, who began plantations in the valley of Chacao, within a league of Caraccas. Dr Sligo followed the example of Blandin, and in a short time this new branch of cultivation was adopted in the valley of Aragoa, and throughout all the provinces. In consequence of the war with England, from 1793 to 1801, when the commerce of South America was destroyed by the English cuizers, the culture of cacao, which does not keep for more than ten months, was in a great measure abandoned by the planters, and that of coffee substituted in its room.

On the Cultivation of Coffee.

Cultivation of coffee.

The coffee plant may be advantageously cultivated within 30 leagues of the equator, where the temperature is never lower than 10° or 12° of Reaumur. The soil should be new and free, and a little elevated, so that the tropical heats may be moderated by the rains. Land composed of hard and cold clay, or light and sandy ground on a bed of marl, should be particularly avoided, as it makes the leaves of the plant turn yellow, and the plant itself either perishes, or becomes barren. In Arabia the soil is rocky, dry, and hot, and in Batavia it is rich and deep. The plantation should be exposed as little as possible to the north, and should be protected from the salt air of the sea, which withers the coffee.

Method of planting.

As soon as the land is well cleaned, holes are made for receiving the plant, at such a distance as the planter thinks proper. The plants are generally placed in parallel rows, though it has been suggested as more œconomical to plant them in triangles. It was generally the custom to place the plants at the distance of four or five feet in every kind of soil; but it has now been found from experience, that this distance should be increased when the soil is more fertile, and that in poor lands it should not be less than 4 feet, and never below 8 feet in the most fertile. The depth of the holes should always be increased with the depth of the vegetable mould, the roots never being permitted to penetrate to the stony ground. In St Domingo, M. Bruley, an eminent colonial proprietor, planted coffee grains at 6 inches distance in a quincunx, in soil prepared for that purpose. When the plants were ready to be transplanted, the ground was well watered, so that when the plant was taken up, its roots were surrounded with earth. In this state they were placed in the holes. The effects of the scorching heat of the torrid zone upon the soil, were tempered by heaping flints round the plants, and by this means a freshness was preserved in the soil even in the driest seasons. The plantations which M. Bruley reared in this manner, produced coffee trees; which were handsomer, stronger, and yielded sooner than those of his neighbours.[*]

The young plants should be two feet high before they are taken from the nursery. They must be covered with earth two inches above their roots, and cut at ten inches above the surface of the earth, leaving nothing but the stem. The best season for planting coffee is before the rains, and it is of great importance that the plants should be lopped off at a certain height, depending on the nature of the soil. In the best kind, they should be trimmed at four or five feet from the ground, and in the poorest land at 2½ feet. The planters of Terra Firma, in general, allow only a height of four feet to the plants. There are many, however, who do not trim them at all, and who permit them to attain their full growth, which is about 25 feet.

Weeding.

During the first two years, the coffee plants must be carefully freed from weeds, and this should be done by the hand rather than with the hoe. Other vegetables may be raised, without any disadvantage, between the rows of coffee plants. In the second year, the plants yield a light crop; and in the third year, they are in full bearing. In Terra Firma, each plant yields about 2 pounds of coffee; in Jamaica 1½ pound; and in St Domingo 1 pound. According to Humboldt, each plant yields in a good soil one kilogramme of coffee, and 960 of them may be planted on a hectare of ground. Excepting at the season of blossoming, the plants require much rain, and care must be taken to preserve them from insects and weeds.

Produce.

As soon as the coffee is ripe, it is the custom in Arabia to spread large linen cloths below the trees, which are shaken from time to time, to detach the ripe cherries from the branches. The fruit gathered in this manner is dried in the sun upon mats, which are made to imbibe their moisture. The dry envelope is then removed from the fruit, by means of a large stone cylinder. The fruit is again placed in the sun, till it is completely free of every particle of moisture. It is then winnowed, and packed up in bales.

---

[*] See *Memoire sur le Cafier*, read at the public sitting of the Lyceè des Arts, 30th Pluv. 1801.

Gathering of coffee.

The English and French colonists follow a different method from the preceding, in gathering their coffee. As soon as the fruit is of a deep red colour, it is reckoned to be ready for being gathered. A large linen bag, kept open by means of a hoop round its mouth, is suspended to the neck of the negroes, who pull the berries with their hands, and, after filling the bag, empty it into a large basket. A single negro can easily collect three bushels in a day. As the berries do not ripen together, they are collected at three different gatherings. One thousand pounds of good coffee is produced from one hundred bushels of cherries just from the tree. The coffee berries may now be dried in two different ways. The first method is to place them in the sun in layers of four inches thick, on inclined platforms, or sloping terraces. In a few days, the pulp is discharged by fermentation, and in about three weeks the coffee is completely dry. The skin of the berries already broken, is removed by mills, or in wooden mortars. The second method is to separate the grain from the pulp at once by means of a mill, and the grains are then left to soak in water 24 hours. They are afterwards placed in the sun to be completely dried. The grains of coffee are next stripped of the pellicle, or parchment as it is called, by means of appropriate mills, and it is afterwards winnowed, and mingled with the grindings and dust of the parchment, in which state it is put into bags for sale.

Dr Titford[*] is of opinion, that coffee should be sent home in the whole berry, without being divested of its pulp. By this means, he asserts that it will retain its peculiar flavour, and will not imbibe any of the bad flavour of sugar, rum, pimento, &c. with which it is generally shipped.

On the Preparation of Coffee.

Preparation of coffee.

As there is perhaps no process which is so little understood, and so uncertain in its results, as that of making coffee, we had determined to treat this branch of the subject at considerable length, and had collected materials for giving a full account of the various approved methods, which have been founded either on theory or experience; but upon examining the method which has been recently published by Count Rumford in his 18th Essay, we were so much satisfied with its superiority to every other, from the numerous experiments and trials which the Count has made on the subject, that we have no hesitation in giving it as the only method which is worthy of being preserved.

As it is of the utmost importance that every part of the process should be carefully and scrupulously followed, we have preserved as much as possible the very words of the Count.

Count Rumford's method of preparing coffee.

"Great care must be taken not to roast coffee too much. As soon as it has acquired a deep cinnamon colour, it should be taken from the fire and cooled: otherwise much of its aromatic flavour will be dissipated, and its taste will become disagreeably bitter.

In some parts of Italy, coffee is roasted in a thin Florence flask, slightly closed by a loose cork, and held over clear burning coals with continual agitation. No vapour issues from the coffee sufficient to prevent the progress of its roasting from being clearly seen. The Count has adopted this process, by using a thin globular vessel of glass, with a long neck, which he closes, when charged, with a long cork, having a small slit on one side, to allow the escape of the vapours, and projecting far enough out of the neck to be used as a handle to turn the vessel round, while exposed to the heat of a chafing dish of coals. This vessel is laid horizontally, and is supported by its neck so as to be easily turned round; which may be done without the least danger, however near the coals, provided the glass be thin, and kept constantly turned.

Roasting.

In order that the coffee may be perfectly good, and very high flavoured, not more than half a pound of the grain should be roasted at once; for when the quantity is greater, it becomes impossible to regulate the heat so as to be quite certain of a good result. The progress of the operation, and the moment most proper to put an end to it, may be judged and determined with great certainty, not only by the changes which take place in the colour of the grain, but also by the peculiar fragrance which will first begin to be diffused by it when it is nearly roasted enough.

If coffee in powder be not defended from the air, it soon loses its flavour, and becomes of little value; and the liquor is never in such high perfection as when the coffee is made immediately after the grain is roasted. This fact is well known to those who are accustomed to coffee in countries where the use of it is not controlled by the laws; and if a government be seriously disposed to encourage the use of coffee, the Count considers it as indispensable that individuals should be permitted to roast it in their own houses. But as the roasting and grinding of coffee takes up considerable time, the author describes a contrivance of a canister to keep it in, which has a double cover. This vessel is a cylinder of tin, having a sliding piston within, of the same material, formed like the cover of a box, but having several slits in its sides, by which they are sprung outwards, and cause it to retain its place in the cylinder with considerable force. The piston, being pressed down upon the coffee, retains it and defends it from the air, while the same object is more completely secured by a common well fitted cover at top. It may be here remarked—that this kind of canister has the advantage of confining the article without including any air in the same space, except what may be diffused between the particles;—but that, with this exception, a well-corked bottle or other fit vessel may answer the same purpose.

Method of preserving ground coffee.

Boiling hot water extracts from coffee, which has been properly roasted and ground, an aromatic substance of an exquisite flavour, together with a considerable quantity of astringent matter of a bitter, but very agreeable taste; but this aromatic substance, which is supposed to be an oil, is extremely volatile; and is so feebly united to the water, that it escapes into the air with great facility.

If a cup of the very best coffee, prepared in the highest perfection, and boiling hot, be placed on a table in the middle of a room, and suffered to cool, it will, in cooling, fill the room with its fragrance; but the coffee, after having become cold, will be found to have lost a great deal of its flavour. If it be again heated, its taste and flavour will be still farther impaired; and after it has been heated and cooled two or three times, it will be found to be quite vapid and disgusting.

The fragrance diffused through the air is a proof, that the coffee has been deprived of its most volatile parts; and as that liquor is found to have lost its peculiar flavour, and also its exhilarating quality, it is inferred, that both these qualities must undoubtedly depend on the preservation of those volatile parts which so readily escape.

---

[*] See the *Transactions of the Society of Arts*, vol. ix.

If the liquid were perfectly at rest, the particles which could escape from its surface would be incomparably less in quantity than would escape by agitation, which would continually present new portions of the fluid to the air. But since all fluids, while heating or cooling, by partial communication, are known to be agitated, the Count endeavours to shew by what means the heat of the liquor may be uniformly kept up in all its parts: for the consequence being, that the parts will, in those circumstances, be at rest, the motions by which the aromatic parts might have been dissipated, will not take place.

By pouring boiling water on the coffee, and surrounding the containing vessel with boiling water, or with the steam of boiling water, the coffee itself will be kept permanently at the same heat, and will not circulate, or be agitated.

The common method of boiling coffee in a coffee pot, is neither economical nor judicious. A large quantity of the material is wasted in this method, and more than half of the aromatic parts, so essential to its good qualities, are lost.

One pound of good Mocha coffee, which, when properly roasted and ground, weighs only fourteen ounces, will make, by proper management, fifty-six full cups of the very best coffee that can be made.

If it be not ground finely, the surfaces of the particles only will be acted upon by the hot water, and the waste will be very great, from the large proportion of coffee left in the grounds.

The size of a coffee cup in England usually answers to 8⅕ cubic inches, but the Count considers the *gill measure* as a proper standard for *a cup of coffee,* which he therefore adopts. This will fill the former cup to seven-eighths of its capacity, and *a quarter of an ounce* of ground coffee will be fully sufficient to make a gill of the most excellent coffee.

It is well known to chemists, that any solvent already in part charged with a substance intended to be taken up, will be less disposed than before to take up any additional quantity; and upon this is founded the process of percolation or straining, as is practised in brewing and other arts, and has been for some time recommended and used in making coffee. To this the Count gives his approbation. He finds, by experience, that the stratum of ground coffee to be laid upon a perforated metallic bottom of a vessel or strainer, ought to be about two-thirds of an inch thick, and to be reduced by pressure by a piston or flat plate of metal (after levelling it) to less than half an inch. From the data he infers, by a chain of observations, that if the height of a cylindrical vessel or strainer be taken constantly at 5½ inches, the diameter of its bottom must be—To make 1 cup of coffee = 1½ inch; 2 cups = 2⅕; 3 or 4 cups = 2¼; 5 or 6 = 3⅕; 7 or 8 = 4; 9 or 10 = 4⅖; 11 or 12 = 5.

These strainers are to be suspended in their reservoirs or vessels for containing the coffee, and the whole included in another vessel called the boiler, which is to contain boiling water kept hot by a lamp, or otherwise. One of the coffee pots recommended by the Count is a porcelain or earthen jug, with a tubular spout, not unlike those which we call milk jugs, except that these commonly have a lip-spout (which would answer nearly as well.) Into the mouth of this is fitted a tin vessel, which fits and descends a little way down. It has a flat bottom perforated with many holes, and a good close cover; and it would be well to have a round plate or rammer, to compress the coffee on its bottom, and defend it from the stream of hot water, when poured in. These several parts are to be dipped in boiling water before using, and the difference between coffee made by this simple and cheap apparatus, of which the mug may also be applied to other uses, and that made by the most perfect machines, will scarcely be distinguishable."

Quantity of coffee exported from different places.

We shall now conclude this article with the following Table, shewing the quantity of coffee exported at different times from Arabia, and the English, French, and Spanish colonies.

		Pounds.	
Cheribon in Java, exported in	1753	1,200,000	
Jaccatra & the Preanger lands	1752	1,200,000	
Ditto do.	1768	4.465,500	
Isle of Bourbon	1768	2,535,100	Raynal.
Surinam exported in	1775	15,387,000	Do.
Martinico		9.688,960	
Guadaloupe		6,302,002	Do.
Cayenne		65,888	Do.
St Domingo exported in .	1767	12,197,977	Do.
Ditto do. in	1775	45,933,941	Do.
Ditto do. in	1783	445,734	quintals.
Ditto do. in	1788	762,865	Do.
Ditto immediately before the French revolution		71,663,187	Edwards.
St Lucia . . . . in	1752	5,000,000	Raynal.
Porto Rico . . . . in	1778	1,116,325	Do.
Grenada . . . . in	1776	1,827.166	Edwards.
Do. . . . . in	1787	987,004	Do.
St Vincent . . . . in	1787	71,041	Do.
Dominica . . . . in	1787	2,032,778	Do.
Do. in favourable years		3,000,000	Do.
Jamaica . . . . in	1768	420,300	Do.
Do. . . . . in	1774	650,700	Do.
Do. . . . . in	1787	716,315	Do.
Do. . . . . in	1790	1,783,740	Do.
Cuba . . . . in	1804	12,000	quintals.
Caraccas . . . . in	1804	5,000	Do.
The Isles of France and Bourbon annually		45,000	Do.
Arabia furnishes annually to the European companies		1,500,000	
Do. . . . . . . Persians		3,500,000	
Do. fleet from Suez		6,500,000	
Do. to Hindostan, the Maldives, and the Arabian colonies on the coast of Africa,		50,000	
Do. to the Caraccas.		1,000,000	
Total from Arabia		12,550,000	

	Quintals.	Value in double piasters.
Imported from the Spanish colonies in America into Mexico, in 1802,	344	6,060
Imported from do. to do. in 1803 . .	474	10,720
Exported from Mexico for Spain in 1802	272	4,360
Quantity produced in eastern Terra Firma, independent of what is used for domestic consumption,	1,000,000 pounds.	

Humboldt computes, that the quantity of coffee annually consumed in Europe is 53 millions of kilogrammes, or 116,971,000 pounds avoirdupois;—that the consumption of France is 230 000 quintals; and that the consumption of Mexico, where the population is one-fifth of that of France, is only 400 or 500 quintals.

COIMBRA, a city of some importance in Portugal, about 31 leagues from Lisbon. The situation of Coimbra is extremely delightful. The surrounding country, though mountainous, is fertile and highly cultivated. The mountains, covered with groves of pines and German oaks, embosom vallies of exquisite beauty, where elegant quintas, and neat summer-houses, are finely contrasted with the stately solemnity of the monastery; and where brooks, flowing through luxuriant gardens, or gleaming amidst the shades of olive-trees, orange-trees, and the beautiful Portuguese cypress, give freshness and animation to the scene. From one of these vallies, through which the Mondego rolls his broad and winding stream, Coimbra rises along the declivity of a hill, bursting at once on the view of the traveller, in all the magnificence of spires, churches, and monasteries. Opposite to Coimbra, in the romantic valley of the Mondego, is the *quinta das lagrimas*, or garden of tears; a spot "over which fancy delights to hover." The view is closed by the lofty mountains of Lousao on one side; and on the other, by the mountain of Bussaco, whose solitary summit is adorned with a celebrated monastery of Carmelites, and its quinta with high shady cypresses.

On entering the town, however, the agreeable feelings and expectations which its situation and distant appearance had excited, are suddenly exchanged for disappointment and disgust. It seems to have been built in meditated defiance of all the rules of convenience and taste. Its streets are extremely narrow, crooked, full of angles, ill paved, and dirty; and frequently so steep that they cannot be climbed without difficulty and toil. The only broad street is in that small part of the town which is situated on the plain; but even that street, as it is deemed unhealthy in summer, is the residence only of the poorer class of citizens. Here are no open spaces, or promenades, so necessary to the health and comfort of the inhabitants in that warm climate. The only resort of the citizens in their pleasure walks is to the great quinta of the Augustines, a spot which all should visit who wish to see the Indian laurels from Goa growing in their greatest perfection. In addition to all these inconveniences, the inns are so bad, their apartments and beds so wretched, and the victuals so execrably dressed, as to give constant exercise to the Christian virtues of patience and self-denial.

Coimbra is a place of great antiquity, and had sustained many sieges before Count Henriquez took possession of Portugal. The ancient walls and towers still remain, and form the only defence of the city. Since the year 1419, it has been in a state of decline. Even yet, however, it contains more than 3000 houses, is divided into eight parishes, and has no less than eight monasteries and eighteen endowments. It is the see of a bishop who is always Count of Arganuil; and has its corregidor, its provedor, and juiz de fora, or court of justice.

By far the most important object at Coimbra is the university, founded at Lisbon by Don Diniz in 1291, but transferred hither after a period of sixteen years. It was again removed to Lisbon; but in 1537 was a second time transferred by John III. to Coimbra, where it has since remained. This university is under the government of a rector nominated by the king. The office of rector, which is never conferred on a member of the university, is triennial; and is generally held by a priest, who, after the term of his rectorship has expired, is either reelected, or promoted to a bishop's see. Superior to the rector is the reformator; but both these offices are frequently united in one person. A *concello dos deoanos*, consisting of the dean of faculty, two fiscals (the conservador and ouvidor) and the secretary, with the rector as president, has the supreme jurisdiction over the concerns of the university. The pecuniary and property transactions of this rich establishment are managed by an auxiliary council of finance, (*juncta de fazenda*) consisting of a professor of theology, a professor of law, the professor of calculation, with a treasurer and clerk. The prior and chief of the Augustine canons regular at Coimbra is *ex officio* chancellor of the university. He is the principal superintendant in matters of learning, conferring the degrees at all promotions, and presiding at the examinations of students. In this university the degrees are very numerous; and, if the division of labour be sufficient to ensure excellence, the professors of Coimbra ought to be particularly eminent. The field of study is here divided into six departments, theology, canon law, jurisprudence, medicine, mathematics, and philosophy. In the first department there are are eight chairs; in the second, nine; in the third, eight; in the fourth, six; in the fifth, four; and four in the sixth. In the department of philosophy, neither logic nor metaphysics have obtained a place; the four chairs being occupied by a professor of zoology and mineralogy, a professor of experimental philosophy, a professor of chemistry, and a professor of botany and economy. Of all the sciences purely philosophical, the law of nature alone is taught by a *professor canonum.*

The session commences in October, and closes in May; after which the public examinations, to which all must submit, continue till the month of July. These examinations are carried on in the Portuguese language; but are so severe that many of the students, rather than submit to them, relinquish the university. The lectures are likewise delivered in Portuguese; and in all respects resemble those delivered in other universities except that the students pay nothing for hearing them. Before a student, whether in theology, jurisprudence, or medicine, can hold a place or exercise his profession, he must have studied at Coimbra a certain number of years, attended certain lectures, and gone through his annual examinations. The term prescribed for physicians is five years; but only those take a doctor's degree, who wish to become tutors at the university, in which case they must dispute publicly, but write no inaugural dissertation. Hence the title of doctor is very uncommon, and of course highly honourable. The degrees of bachelor or master of arts are now seldom conferred. The number of students at Coimbra is very considerable. When Link was there, in 1798, he was told that it exceeded 800; though some Portuguese writers make their number amount to 2000, and others even to 8000. The students are distinguished by a particular dress, but live, as with us, in private houses, and not within the walls of the university.

The museum contains few remarkable specimens; but the collection of philosophical instruments is excellent, containing many of English manufacture, entirely new. In mechanics it is very rich, but extremely poor in electrical apparatus. The chemical laboratory is capacious, and well furnished; containing, besides the objects generally found in such establishments, a pneumatic apparatus, and a collection of chemical preparations according to the new nomenclature: it is likewise provided with a collection of chirurgical instruments. In the library the number of volumes is considerable, comprising many of the most valuable modern publications. The observatory, which stands in an excellent situation in the upper end of the town, is very convenient and neatly arranged; but very deficient in instruments. The botanic garden, though not large, is admirably regulated, forming almost an exact counterpart to the garden of Paris. Besides many exotics, it contains a considerable number of plants indigenous in Portugal. In short, the institutions in the university of Coimbra are far from being contemptible; nor are its professors deficient either in genius or learning. But the difficulty and the danger of publishing, in a country where every work must be printed at the expence of the author, without any prospect of recompence, and where the inquisition reigns in all its terror, repress all their exertions, and retard the progress of literature and science. West Long. 8° 23′ 45″, North Lat. 40° 12′ 30″. See Link's *Travels in Portugal*. (*k*)

COIN. See BULLION, CURRENCY, and MONEY.

COINING MACHINERY.

COINING, is the art of making metal money, by impressing on its surface such marks as will, at first sight, identify it to be the legal coin, issued by the government of the country where it is current. The impression should be so executed as not to be easily effaced by use, or imitated by counterfeits, and that it should not admit of any reduction from the coin without evidently disfiguring it.

Of hammer money.

Coining press.

Coining among the ancients, and indeed by the moderns, till within these 250 years, appears to have been very rudely and imperfectly performed, by placing the blank piece of money between two dies, or steel punches, containing the design of the coin, and striking upon the upper one with a hammer. This, which is called hammer money, is alway imperfect, from the uncertainty of placing the two dies exactly over each other, when the blank money is between them; and also from the improbability of a man being able to strike a blow with such force as to make all parts of the impression equally perfect. The hammer money continued to be current in England, until the reign of William III. although the more perfect method of coining, by the mill or press, was introduced from France, in the reign of Queen Elizabeth, as early as 1562. The mill did not continue in practice more than 10 years, when the hammer coinage was resumed as being less expensive. Before the hammer money was called in by William III. the English money was in a most wretched condition, having been filed and clipped by natives, as well as foreigners, until it had lost nearly half its value. The milling upon the edges of coins was introduced about this period, (William III.) and such confidence was then placed in this new device, that it was deemed impossible for the coin to be diminished, by clipping or wearing. It was, however, soon discovered, that milled money, either of gold or silver, could be diminished with great facility and expedition, by a process termed *sweating*, which was effected by disolving a portion from the whole surface of the coin, by an acid, without leaving any evident marks of the fraud. The money was also filed on the edge, and a new milling afterwards impressed upon it, by methods which were soon discovered, notwithstanding the great caution taken by the government to keep the process of milling a profound secret.

Invention of the press.

The coining press, or mill, is of French origin, and is generally ascribed to Antonie Brucher, an engraver, who, in 1553, first tried it in the French king's (Henry II.) palace, at Paris, for the coining of counters. It continued in use till 1585, in the reign of Henry III. when it was laid aside on account of its being a more expensive method than the hammer coinage. Queen Elizabeth, as we before stated, had a coining press very soon after its first invention, but she soon gave it up for the same reason as the French did. The machine remained in disuse untill 1623, when Briot, a French artist, who was unable to persuade the French government to adopt it again, came to England, where it was immediately put in practice under Briot's direction, who was appointed chief engraver of the mint. Like most other new inventions, it was sometimes used, then laid by, and the hammer resumed during a period of 40 years. But under Charles II., in 1662, the use of the press was completely established in the English mint, as it had been by the French, in 1645; and from the improvement it has made in the neatness and perfection of the coins struck by it, there is no danger of its ever again falling into disuse, especially as the admirable improvements made in it by the late Mathew Boulton, Esq. have rendered it the cheapest possible method, as well as the most perfect. These improvements, which we intend to describe in this article, have been adopted by England, Denmark and Russia, after having being long used at Mr Boulton's works, at Soho, in coining copper, by contract, for many of the governments in Europe; for the East India Company, and the Americans. By their steam engines, they work the presses for cutting out the circular pieces of metal, and afterwards by other presses both faces at once, with such superiority of execution, and cheapness of workmanship, as will greatly prevent clandestine imitation. By this machinery, four boys are capable of striking 20,000 pieces of money in an hour, and the machine acts at the same time as a register, keeping an unerring account of the number of pieces struck.

Old method of coining in the Tower.

The coinage of England, from the time of William the Conqueror until 1811, was wholly carried on, in the Tower of London, by a corporation, under the title of the Mint, consisting of a number of officers, each having their respective duties in the different processes of the coinage. The artizans or workmen were called the Company of Moneyers, and did the work by contract. See MINT.

They employed four kinds of machines; 1st, The rolling mill for laminating the metal to plates of a proper thickness; The cutting out machine, for punching circular pieces from the plates, of the proper size to form the coin; 3d, The machine for milling on the edges; and 4th, The coining press for stamping the impression on both sides at once.

Casting the ingots.

Laminating.

Cutting out blanks.

Plate CCI, Fig. 6.

The first operation is the mixing of the metal, because there is no coin of pure gold or silver, a quantity of copper or alloy being always mixed with them, to render the coin harder, and less liable to be diminished by fraud. When the metal is mixed in crucibles, and melted in an air furnace, it is cast into long flat bars or ingots, by the same methods as are used by founders in sand, both with regard to the frames, the manner of working the earth, and the use of the models or patterns. These patterns are flat plates of copper about fifteen inches long, and nearly the thickness of the coin to be struck. The bars or ingots, when taken out of the moulds, have the sand scraped and brushed off; and are passed several times through the rollers of the mill, to flatten and bring them to the just thickness of the specie to be coined. Before the ingots of gold are passed through the mill, they are *annealed*, that is, they are heated red in a furnace, and plunged in water, to soften and render the metal more ductile. The silver ingots pass through the mill, just as they are, without any annealing, but are afterwards put into the furnace and left to cool gradually. The plates, whether silver, gold, or copper, being thus reduced as near as possible to their thickness, are cut into round pieces called blanks or planchets, very near the size of the intended specie. This is done with a machine similar to that called by mechanics, a fly press; see Fig. 6. Plate CCI. It consists of a proper iron frame AA, supporting a perpendicular screw B, which has a handle C at the top to work it by, and at the lower end is a cylindrical steel punch *a*, of exactly the same size as the pieces intended to cut out. When it is depressed by the screw, this punch or cutter enters a hole made in a steel dye or bed *b*, which hole is exactly the size of the punch. The slip of plate D being placed over this hole, and the screw turned by its handle, forces the punch through the plate, carrying a round piece with it. The workman guides the plate D with one hand and works the screw C with the other, so as to cut out the pieces with great rapidity.

Adjusting.

These pieces are now given to proper officers to be adjusted, and brought by filing the edges to the weight of the standard, whereby they are to be regulated: the remainder of the plate between the circles is melted again under the denomination of *sizel*. The pieces are adjusted in a fine balance; and those which prove too light are separated from those which are too heavy, the first to be melted again, and the second to be filed down; for the rollers of the flatting mill, by which the plates are reduced, are never so exact, but there will be some inequality in the thickness, causing a difference in the blanks, which inequality may indeed be owing to the quality of the matter, as well as of the machine, some parts being more porous than others.

Blanching.

Milling the edges.

Plate CCI Fig. 7.

When the blanks are adjusted, they are carried to the blanching or whitening house, where they have their colour given them; and the silver ones are whitened, which is done by heating them in a furnace, to anneal and soften the metal, and when taken out and cooled, they are boiled successively in two copper vessels with water, containing common salt and tartar, and after that they are scoured well with sand, and washed with common water, then dried over a wood fire in a copper sieve, into which they are put when taken out of the boilers. The planchets are now marked with letters, or graining on the edge, to prevent the clipping and paring of the specie, which is one of the ways wherein the ancient money used to be damaged. The method of performing this operation, in the English mint, is by its very constitution kept a profound secret; but is shewn publicly in the mints of foreign countries. The machine, used by them, for marking, or milling the edges, is very simple, yet ingenious; see Plate CCI. Fig. 7. It consists of two plates of steel, *aa* and *bb* in the form of rulers, and about the same thickness as the coin. On the adjacent edges of these the legend or edging is engraved, half on the one, and half on the other. One of these rulers *aa* is immoveable, being strongly bound with clamps to a copper plate *dd*, and that again is fixed to a strong board or table AA. The other plate *bb* is moveable in the direction of its length, and slides on the copper plate *dd*, by means of a handle B, and a pinion D; the teeth of which catch into the teeth of a rack *ee*, attached to the moving ruler *bb*. The distance between the edges of the two rulers is made to correspond with the diameter of the money, by advancing the immoveable ruler towards the other by two screws *f*, *f*. Now the blank being placed horizontally between these two rulers, is carried along by the motion of the moveable one, so that by the time the handle B has made half a turn, it is found marked all round. The Figure shews that the machine will do two blanks at once.

This machine is so easily wrought, that a single man is able to mill twenty thousand blanks in a day. Savary says it was invented by the Sieur Castagin, engineer to the French king, and first used in 1685. But it is certain we had the art of lettering the edges in England long before that time. Witness the crowns and half crowns of Oliver Cromwell, struck in 1658, which, for beauty and perfection, far exceed any French coins we have ever seen.

Coining b the press.

Plate CC Fig. 8.

The planchets being thus prepared, are to be stamped in the coining press, shewn in Fig. 8. of Plate CCI. This machine has a massive iron frame, consisting of two upright sides or cheeks, AA, united by cross pieces or sills, B and C, at top and at bottom. Through the top piece B, a strong perpendicular screw D works in the center of the frame, and actuates the upper die or steel matrix *a*, on which the impression of the coin is engraved or sunk; this die is fixed in a square slider E, moving in collars *b*, *b*, attached to the frame A, so that it merely rises and falls by the movement of the screw, without turning round. The lower die *c*, is fixed in the center of the bottom sill C of the press, being held in a box furnished with screws to adjust it immediately beneath the upper one. The press is wrought by four men. The screw D has a lever, or pair of arms F, F, fixed on the top of it, called by the French *balancier* or fly, from being loaded at the ends with heavy weights *d*, *d*; and the men pull by ropes or straps G, G and H, H, fastened at the ends of these arms; another person sits in a hole in the floor before the press, and places the blanks, one by one, upon the lower die *c*, then the two men, by the ropes GG, give a sudden motion to the arms of the fly *dd*, which turning the screw D, presses the upper die upon the money with sufficient force to give it the impression, the momentum acquired by the motion of the weights of the fly giving it a very great power. The recoil of the press, aided by the two workmen who hold the two shafts HH, returns the arms of the fly; then the person beneath puts in another blank, which is struck as before, and in this manner the operation proceeds very rapidly. The blanks having now all their marks and impressions, both on the edges and faces, become money; but they have not currency till they have been weighed and examined by proper officers belonging to the establishment.

The new Mint.

Mr Boulton's inventions.

In 1811, the Royal Mint was removed from the Tower of London to a very magnificent building erected for the purpose on the east side of Tower-hill, from the designs of Mr Johnson, architect. The system of coining by machinery, practised in this new establishment, was, in great part, invented by the late Matthew Boulton, Esq. His original apparatus was erected at his celebrated works at Soho, near Birmingham, in 1788 and 1789, and was first employed in coining for the East India Company, and some of the earliest copper coins issued by the French republic. The beauty of the coins which he produced, occasioned him to be employed by contract by our government, to coin the new copper issued in 1797. Since this period, he has recoined an immense number of Spanish dollars, without remelting them; also copper for the East India Company, and several foreign governments; which shewed the advantage of the invention to be so great, that the governments of Russia and Denmark, each procured a complete series of machines from Mr Boulton, under the sanction of acts of Parliament, and erected them in their Mints at Petersburgh and Copenhagen. In the new Mint erected on Tower-hill, a complete set of Mr Boulton's machines have been at work since 1811, with great success.

Plates of the machinery.

Knowing that it would be highly interesting to our readers, we have obtained a series of drawings of these machines, which are contained in Plates CC. CCI. CCII.

Pouring machine.

Plate CC. Figs. 1, 2, 3, 4, and 5.

The first of these, at Figs. 1, 2, 3, 4, and 5, contains drawings of the crane, and pouring machine which lifts the melting pots out of the furnace, and pours their contents into the ingot moulds.

Rollers.

Figs. 6 & 7.

Circular shears.

Plate CCI. Fig. 4.

Figs. 1, 2, and 3.

Coining press.

Figs. 6 and 7, are the laminating rollers, used for flattening out the ingots into plates of the proper thickness: these plates are cut into narrow slips by the circular shears shewn in Plate CCI. at Fig. 4. The strips are afterwards rolled again, to reduce them to the exact thickness of the intended coin. From these plates circular pieces of blanks are cut out by the machinery represented in Figs. 1, 2, and 3; and after being properly blanched and scoured, have their impressions struck in the press represented in Plate CCII.

Melting.

Plate CC. Fig. 1.

Crane.

The furnaces in which the metal is melted, are eight in number, and are so arranged on opposite sides of the melting-house, in two rows of four in each, that the crane, represented in Fig. 1, Plate CC. being placed in the centre between four, will, by turning round upon its center, come over the center of any one of the furnaces, and will lift a pot of melted metal from any one of the four; therefore, two cranes so situated, will command the whole. The crane consists of a vertical column AB, fixed firmly in the ground with a flanch at its base; round this the gib C, D, E swings, being united by two collars at C and E, so as to swing freely all round; *e* is a frame of iron, bolted to the gib to support the pivots of the roller or barrel *f*, and also the axis of the pinion *g*, which works the cog-wheel *h* on the end of the barrel; the chain from the barrel passes over the pulley F fixed at the top of the gib, immediately over the center of the column, and thence proceeds to the pulley D at the extremity of the gib. The frame *e* also supports a third axis *i*, having an endless screw upon it, acting in the teeth of a wheel, fixed upon the main column, so that by turning the winch *k* at the end of this spindle, the whole crane is turned round on its axis. At the extremity of the chain, a pair of tongs G are suspended, the claws of which take hold of two projecting ears of the melting pot, and then it is lifted out of the furnace by turning the handle of the pinion *g*; then by turning the winch *k*, the crane is swung round, and the pot is conducted to the pouring machine.

Pouring machine.

Plate CC. Figs. 5.

Ingot moulds.

Fig. 4.

This machine has an iron frame HH erected from the floor, to support the two pivots *l* of a frame or cradle which receives the melting pot I, and on which pivots it can be inclined by means of an arch K and proper wheel work, so as to pour its contents into the ingot moulds, which are placed in a carriage L, (shewn separately in Fig. 5). The cradle for the melting pot is composed of an axis *e* on which it swings; a bar *m* proceeding from it, and having the rack K fixed to it at the lower end; also an iron hoop *n*, which embraces the pot round the neck, and has two bars *o* proceeding one on each side to the lower end. The hoop *n*, as well as the latter bars, are united to the axis and the bar *m* by hinges, so that they will open out to receive the pot, but being drawn together by a screw in the hoop at *n*, hold it quite fast: The teeth of the rack K are engaged by a pinion *p*, situated on an axis which goes across the frame, and receives its motion, by equal bevel wheels, from an axis *q*, which is moved by means of equal bevel wheels upon the end of a third axis, parallel with the first; at its opposite extremity this carries a wheel *r*, which is turned by a pinion *s* having a handle at the extremity of its axis. The object of this train of wheels is, that by turning the handle of the pinion *s*, the workman will be able to incline the rack and melting pot with a very gradual motion, to empty its contents into the moulds. The ingot moulds are made of cast iron, as shewn in Fig. 4, each in two separate halves A, B, having flat surfaces A, B to form the body of the ingot, and rising edges *ab* composing the sides of the mould; one of the halves has also a similar rise *c* to make the bottom, so that two halves, when put together, form a proper cavity or mould to cast an ingot, as is shewn in Figure 1, which represents the two halves put together ready for casting.

Fig. 2.

Fig. 3.

Fig. 1.

Figs. 2 & 3.

Fig. 1.

Fig. 3.

The moulds are set up, a great many of them together, in an iron frame mounted on a carriage, shewn sidewise in Fig. 2, and endwise in Fig. 3. The carriage is an iron plate LL, moving on four wheels, and having the iron frame MM, NN for the moulds upon it. This frame has two screws *tt* at each end, which being forced up against the moulds P, placed in the frame, hold them all together and in their places, so as to make all the joints tight; they rest upon an iron plate, suspended by two screws *vv*, by which it can be elevated or depressed at pleasure, to suit moulds of different sizes. The carriage runs upon a railway laid across the floor of the melting-house, so as to bring it beneath the pouring machine, as represented in Fig. 1. In this situation, a rack *w*, Figs. 2 and 3, which is fixed to the carriage by small columns, comes where its teeth will engage with a wheel *x*, Fig. 1: This is turned round by a pinion, carrying the handle *y* on the end of its spindle; and therefore by turning this, the wheel *x* communicates a gradual and regular motion to the carriage, bringing the moulds, one by one, beneath the lip of the melting pot to be filled with metal. The distance of the moulds from the pot, can be regulated at pleasure by shifting the frame MN sidewise upon the carriage, which is done by means of a screw at each end, as shewn at W, Fig. 3.

Furnaces.

The furnaces in which the metal is melted are extremely well contrived, having the flues for the draught into the chimney proceeding from three different sides towards the top, instead of going altogether from one side, as in common air furnaces, by which means the heat is much more regular, and has not so much tendency to burn away in the throat or flue, as if it were single.

Melting pots.
Plate CC.
Fig. 5.
Melting.

The melting pots, Fig. 5, are made of cast-iron, and of sufficient capacity to hold 400lbs. of metal. They have each a lip or spout *a*, at which the metal is poured out, and two ears *b*, *c*, by which they are taken up with the tongs of the crane, as before described, and lifted into the furnaces. The pot is supported by proper pedestals from the grate of the furnace, and has a large ring of cast iron placed on the top of it to prevent the fuel from falling into it: As soon as it arrives at a red heat, the metal, properly prepared and mixed, is put in, and occasionally stirred up while it is melting, which takes some hours. The moulds, in this interval, are prepared by warming them in a stove, and when they are taken out to be placed in the frame upon the carriage, the inside surfaces are severally rubbed with a cloth dipped in oil, which preparation, as well as the heating, is found to give the ingot a better surface. When the proper number of moulds are placed in the carriage, as shewn in Fig. 2, the screws *t*, *t* at the ends, are screwed fast to fix them all tight; and in this state they are prepared for casting.

Fig. 2.

Casting.
Fig. 1.
Assay.

The pot of metal, as before mentioned, is lifted out of the furnace by the crane, then swung round, and lowered down into the cradle *lmno* of the pouring machine, until the ring on the edge of it rests on the iron hoop *n*, which being screwed up tight, holds it fast, and the tongs of the crane are disengaged. One of the attendants now takes the handle *s* in one hand, and *y* in the other; and by turning the latter of these he advances the carriage forwards to bring the first mould beneath the lip of the melting pot, then by turning the other he inclines the pot, and pours the metal into the mould; when this is full, the second is brought beneath it, and so on in succession. The whole four hundred weight is very quickly cast into ingots without any loss or waste, which could scarcely be avoided in any other way of casting. The first metal which is poured from the pot is received in a small iron spoon, and is reserved for the assay master, who examines its quality, and it is not allowed to pass through the succeeding processes, until, from this specimen, he has ascertained it to be standard. A second sample is taken from the middle of the pot, and a third from the last of it. The pouring machine was, we understand, invented by Mr Morrison, an officer of the Mint.

Rolling mill.
Plate CC.
Figs. 6 & 7.
Fig. 6.

The ingots thus cast are about 10 inches long, 7 broad, and 6 tenths of an inch thick. They are next carried to the rolling mill, which is represented in Figs. 6. and 7. in Plate CC. In the former, A represents a large cog wheel, fixed on the extremity of a long horizontal shaft BB, extending beneath the whole mill: This wheel and shaft receive their motion from a smaller wheel, fixed on the main or flay wheel shaft of steam engine of 36 horse power. The main shaft B of the rolling mill has wheels C, D, E fixed upon it, to give motion to the respective rollers, which are mounted at F and G, in strong iron frames bolted to the iron sills *a a*, which extend through the whole length of the mill, and rest upon the masonry, in which the wheels are concealed. The two large wheels C and E give motion to the wheels H, I, which are supported on bearings between two standards *b b* bolted down to the ground sills; as is also shewn at *b b* in the perspective view, Fig. 6. On the ends of the axes of these wheels are heads for the reception of coupling boxes *d d*, which unite them to short connecting shafts K, L; and these again, by means of coupling boxes, convey motion to the upper rollers *ee* of each pair, at F and G. The middle wheel D upon the main shaft B gives motion to the lower rollers in a similar manner thus: It turns the wheel M, by means of an intermediate wheel, not shewn in the Figures. This at each end of its axis, gives motion to the lower rollers FF by the connecting shaft *g g*. By this ingenious arrangement, both the rollers *e*, *f* of each frame, receive their motion from the main shaft with equal velocity, and by means of wheels of large radius, which act with much more certainty than the small pinions usually employed in rolling mills, to connect the upper and lower rollers, and cause them to move together. The wheel M, in consequence of its intermediate wheel, revolves in a contrary direction to the wheels H, I; but all the pairs of wheels being of equal diameters, and having the same numbers of teeth, they revolve in precisely the same period; and the two rollers *e*, *f* being of the same diameter, their surfaces accompany each other, without which the metal rolled between them would be buckled; that is, one side being more expanded than the other, would render the plate convex. The connecting shafts K, L and *g g*, and coupling boxes *d d*, which give motion to the rollers, have sufficient play in their joints, to allow that small deviation which takes place, when the rollers are set nearer together for reducing the plate to its intended thickness. The detail respecting the frame, and parts of the rollers, is explained by the perspective view, Fig. 7. in which *a* represents one of the sills before mentioned, which runs through the whole length of the mill; upon these are bolted the two cheeks, or side frames of the rollers, marked NN: Each of these has a large mortise, or opening in it, to receive the bearings for the necks or gudgeons of the rollers *e f*, between which the metal is passed. Their distance from each other, and consequently the thickness of the rolled plate, is regulated by two strong screws OO, passing through the upper part of the cheeks of the frame, and their points pressing upon the bearings PP, or the pivots of the upper roller. The weight of the roller is suspended by two bolts, passing through the frame, and they are united to a collar Q, which is fitted on the upper end of the screws; and this collar being a long plate, is common to both screws, as the Figure shews. Immediately above this plate, the screws have wheels RR fitted upon them, which are cut with teeth on the lower part of them, to receive motion from two endless screws, formed upon a spindle SS, which moves in bearings projecting from the plate Q. By turning this spindle, its endless screws act upon the wheels RR, to turn them round; and the great screws partaking of the same motion, elevate or depress the upper roller *e*, with so delicate a movement, that it can be adjusted to roll the plate to the greatest nicety; and the adjustment being made at both ends at the same time, the two rollers always preserve their parallelism. The metal, when introduced to the rollers, is placed upon a small table V, fixed between the frames NN. Its upper surface being exactly level with the top of the lower rollers, it is fastened by means of a cross bar T, and wedges which press it fast up against projecting pieces of the frames.

Plate CC.
Fig. 6.
Fig. 7.

The cheeks NN of the frame, are connected by strong wrought iron bolts, which are too plainly shewn in the figure to require any particular description.

Fig. 6.

The rolling mill contains four pair of rollers, each driven by its train of wheel work as shewn in Fig. 6; the mill therefore consists of two such sets of wheels and rollers, as are represented in Fig. 6. The two shafts are situated parallel to each other, and receive their motion from the same steam engine; the wheel before mentioned, which is on the main axis of it, being situated between them, and giving motion to one of the main wheels AA on each side. The whole machine forms the most complete rolling mill we have ever seen, and the workmanship of it is unrivalled: It was executed by the celebrated engineer John Rennie, Esq.

Operation of rolling.

Circular shears.

PLATE CCI. Fig. 4.

Fig. 4.

Fig. 5.

Adjusting rollers.

PLATE CC. Fig. 8.

Gauge.

The ingots of silver are heated to redness in a furnace before they are rolled. The two furnaces for this purpose are situated before two pair of rollers, which are therefore termed breaking down rollers, being used to consolidate the metal by rolling whilst hot. In the operation, two men are employed; one takes the metal from the furnace by a pair of tongs, and introduces it between the rollers; the other catches it as it comes through, and lifting it over the top roller, returns it to the first, who puts it through again, having previously turned the handle S a small quantity, to set the rollers nearer together. After having been rolled in this manner four or five times, they are reduced to near two-tenths of an inch in thickness, and increased in length to about four times the breadth of the ingot; for it should be observed, that the ingots are rolled across their breadth, the longest side being presented to the rollers; and as the rollers do not extend the plate sidewise, the plates, when finished, are as broad as the length of the ingots, viz. 10 inches, and three or four times as long as the breadth of the ingot, *i. e.* from 21 to 28 inches. These plates, whilst still warm, are rubbed over with a weak solution of acid or *pickle*, to remove the colour produced by the heat, and are then cut up into narrow slips across the breadth of the plate, by means of the circular shears, Fig. 4. Plate CCI. This machine is worked by a cog wheel at the extremity of the main shaft B, Fig. 6. of the rolling mill. It consists of a framing of iron AA, supporting two shafts BB, which are parallel to each other, and move together by means of two equal cog wheels CC, the lower one of which works with the teeth of the great wheel above mentioned, upon the main shaft of the rolling mill. At the extremities of the two shafts, wheels or circular cutters are fixed, their edges overlapping each other a small quantity, as is shewn in the edge view Fig. 5. Here it is seen that each cutter has a rim of smaller diameter than the outside: this small rim in the top cutter is behind it at *e*, but is in front of the lower one at *g*, so that the adjacent edges of the large rims *f* and *k* come in contact, and overlap each other a small quantity. By this means they act in the same manner as shears, to cut any thing, as *c*, *d*, which is interposed between them, by depressing one half *d*, and elevating the other *c*, till they are completely separated. F, Fig. 4, represents a shelf on which the plate is laid, and advanced forwards to present it to the cutter; and G is a ledge or guide, screwed down upon it, to guide the metal, and, by its distance behind the planes of the cutters, to regulate the breadth of the piece which shall be cut off; for this purpose the screws which fasten down the ledge are fitted in oblong holes, which admit of small adjustment. The workman holds the plate flat down upon the surface F, and advancing it towards the shears, they will continue to draw it through, when they once take hold, until they have cut the whole length. *c d*, Fig. 5. shews a section of the plate to explain the manner in which it is cut: The part *c* is conveyed upon the top of the rim *k* of the lower cutter, and kept down from rising by the small diameter *e* of the upper cutter; at the same time, the other part of the plate is depressed by the rim *f* of the upper cutter, and supported by the small rim *g* of the lower one. By this means, the divided parts *c* and *d* are prevented from curling up into scrolls, as they will, when cut in a common pair of shears, because the small parts *e* and *g* keep them straight. Behind the standard, supporting the back pivots of the shafts BB of the cutter, is a frame *l*, with a screw *m* tapped through it. This is used to draw the axis of the upper cutter D endwise, and keep its edge in close contact with the edge of the other cutter E. The slips of plate are now carried to the other two pair of rollers in the rolling mill, which are made of case-hardened iron, and with a better polish on their surface than the breaking down rollers. The plates are passed cold between these, to bring them exactly to the requisite thickness; hence they are called the adjusting or planishing rollers. The workman here tries every piece as it comes through by the gauge Fig. 8. This is a piece of steel, having a notch in it, the inside lines of which are very straight, and inclined to each other at a very acute angle. They are divided, as is shewn in the Figure, so that the edge of the plate being pressed into the notch, will have its exact thickness determined by the distance it will go into it, the divisions shewing the dimensions in parts of an inch.

PLATE CCI. Fig. 6.

In rolling the plate the second time, they pass all the slips successively through the rollers, then adjust the rollers by the handle, and pass them all through a second time. This is repeated three or four times, and the last time they are every one tried by the gauge, and sorted by it into as many parcels as they find different thicknesses; for it is a curious fact, that though the rollers are 14 inches in diameter, and the frame proportionally strong, still they will yield, in some degree, so as to reduce a thick plate in a less degree than a thin one; and the plates which have all passed through the same rollers will be of three or four different thicknesses, which being sorted by the gauge into as many parcels, they begin to reduce them to the exact quantity, by setting the roller according to each parcel: then the first of the parcel which comes through is tried, by cutting out a circular piece with a small hand machine, Fig. 6. Plate CCI. and weighing it: If it proves too light or too heavy, the rollers are adjusted accordingly, till, by a few trials, they are got right, and then all the parcel is rolled through. The next parcel is then tried, and so on; the trial plates which are too thin being returned as waste to the melting house. By these precautions, the blanks when cut out by the next machine will be very nearly all the same weight, which they would scarcely be even if the gauge determined all the plates to the same thickness, because some being more condensed than others, they could not all have the same specific gravity.

Cutting out machine.

PLATE CCI. Figs. 1, 2, and 3.

Fig. 2.

The cutting out machine is explained by Figures 1, 2, and 3, Plate CCI. or at least sufficient is there shewn to describe the whole. A A is a basement of stone to support an iron plate B B. On this, columns C C are erected to sustain the upper part D of the frame. The iron frame of the machine, marked EEF, is fixed down upon the iron plate B: it has a screw *a* fitted through the upper part, which acts upon a slider *b*, supported by a cross bar *c* of the frame: it is cylindrical, but has a leaf or fillet on the front side, to prevent it from turning round. The punch *d* is fixed in the lower end of it, and immediately beneath it is the die or bed *e*, which is adjustible, by screws, to its true position. These parts are very nearly the same as the original cutting out machine; but the manner of actuating it, by the power of a steam engine, instead of hand labour, constitutes the improvement. Above the screw is an axis G, fitted on the top of the screw, with a socket, and the upper end supported by the frame D: above this support, a lever N H is fixed to the axis, to receive the action of cams or wipers fixed on a large horizontal wheel, situated behind the machine. This wheel is shewn in Fig. 2, in which K K is a plan of part of its rim, and L one of its cams.

Plate CCI. Fig. 3.

Fig. 1.

Fig. 1.

In its revolution, it intercepts the roller *g*, at the extremity of the lever H, and by moving it outwards, raises up the screw; but the moment it has passed by, the screw is returned, to cut the plate, by the re-action of a spring, which draws the rod M. This is attached to the arm N, of the lever HN, and therefore draws the roller *g* back the instant the cam has passed by. The rod M draws from a link *m* fitted upon the arm N of the lever, and moveable along it by means of a screw *p*, so as to adjust the power of it at pleasure, by throwing its action at a greater or less distance from the centre of motion G. The motion of the machine can be discontinued at pleasure by means of a catch, Fig. 3; it is marked OP, and moves on the centre P, being constantly pressed upwards by the spring *r*. This catch is situated crosswise beneath the arm N of the lever, and when that lever comes back, the hook O catches and holds it up, so as to prevent its return. When the machine is required to work, the string *s* is pulled, to draw down the catch beneath the plane of the lever's motion. This string, as shewn in Fig. 1, comes down to a treddle R, on the ground, before the machine. The boy who attends the machine, places the plate over the bed *e*, and puts his foot on the treddle when he wishes the machine to work. This relieves the lever N from the catch, and then, every time the cam of the wheel K comes by, it lifts the roller *g*, and raises the punch; but as soon as the cam has passed, the spring makes a stroke, and cuts out a piece of plate, which drops through the bed, and falls out at a spout T. The instant he relieves the treddle, the machine stops, but still the point of the cam strikes the roller *g* every time it comes by. This is avoided when the machine is to be permanently stopped, by the following means: The centre P, of the catch O P, is fixed at the end of a lever, moving on a centre W, Fig. 3, and having a long handle W X, Fig. 1; therefore in pulling this lever, the catch is drawn forwards, and raises the roller *g* quite out of the reach of the cam L. The lower end of the lever, Fig. 1. moves in a notch in the plate B, and thus retains it when it is drawn forwards. Z is a lever fixed on the axis G, and carrying a sweep, or arch, at the extremity of which is a weight or fly *w*, to give impetus to the stroke of the machine; this is checked, when, at the end of its motion, it strikes against a strong vertical wood spring Y, firmly fixed to the framing. The two wheels *x*, which are indented into each other, are to connect the axis G with the socket fitted at the top of the screw *e*, and there admit of adjustment, by turning the screw round a small quantity, with respect to the lever H, to give a greater or less motion to the screw. The Figure shews the clamps which hold the wheels together. The Figures in our Plate, though they explain the construction of the machine, do not exhibit the real appearance of it, because there are twelve of these machines, all mounted on the same frame. They are contained in a very elegant circular room, lighted by a skylight, in the centre. The stone basement A A, Fig. 1, is a circular wall, and the plate B; a ring surmounting it; there are twelve of the columns C supporting a circular iron ring, or frame D; and this has some curious cross framing in it, to support the axis of the wheel K K: this, of course, is common to all the twelve presses, which are situated between each pair of the columns C. An immense horizontal fly wheel is fixed on the axis above the wheel, to regulate the motion. The springs of the rods N, are concealed within twelve columns, which ornament the room, and appear to support the ceiling. The whole is moved by a steam engine of sixteen horse power.

Adjusting the blanks.

The blanks thus cut are next to be adjusted by filing the edges, to bring them to the exact weight; but by the system adopted in the last rolling very little adjustment is requisite, and as soon as this is performed, the edge is milled. This operation, as before mentioned, is not shewn in our mint; but we believe Mr Boulton has improved this process as well as the others; at least some of his coins have milling of a kind very different from any other, and which, we think, could not be done by the machine we have represented in Plate CCI.

Boulton's coining press.

Plate CCII.

Fig. 5.

Fig. 2.

Fig. 1.

The coining press, which is the most beautiful machine of the whole series, comes next to be described, (see Plate CCII,) which is a perspective view of one of the presses complete: AA is a solid stone basement supporting the whole; upon it are erected four columns, rising to the ceiling of the room, and in the centre between these, the press is placed. Its frame marked KK, is screwed down by four bolts shewn at the bottom; *b* is the screw, or rather the spindle of it, the screw itself being concealed within the frame of the press. On the top of the spindle, the fly DB is fixed, and over this a hollow spindle C, like an inverted trumpet, conveying the motion to the press, from machinery contained in the apartment above. The weights BD, at the extremities of the arms of the fly, are limited in the quantity of their motion, by checks affixed to iron beams E and F, extending from one of the columns to the other: These receive the blow of the fly, in case the press should ever make a stroke without a blank being between the dies, and are therefore made exceedingly strong; the columns are of oak. The recoil of the fly, after having struck a coin, is checked by its coming against a piece of wood G, which is fitted into the tube H, fixed to the iron beam E, and having a concealed spring to ease the blow. The upper or moving die is beneath the screw; for this press has no slider like the old one, but the die turns round with it whilst it is making the impression. The screw *b b* is, as the Figure shews, cylindrical at each end, and is fitted in very accurate bearings, adjustible by screws at *a a* above, and at *c c* below; between these it is cut into a worm or screw, and is received in a proper nut, but it depends on this only for its ascent and descent, the fittings at the ends keeping it truly vertical. Fig. 5. explains, by an enlarged view, the connection of the upper die with the screw at this place; *b* is the lower point of the screw; it has a ring *d* fixed on it, having a leaf or tooth projecting downwards, and entering a recess made in a ring *e*, of similar dimensions, which is the upper part of a piece *f*, forming a box, furnished with screws, to hold the upper die; the point of the screw acts upon this piece, and to keep it always in contact therewith, the ring *e* is suspended in a collar *g*; this has two arms, to which bolts *h h* are united by screws; and these bolts (see Fig. 1.) passing up through holes in the solid frame, are united to another collar *k*, which fits on the screw, and rests upon a shoulder formed on it; so that by the adjusting screws on the rods *h*, the collar is always kept tight, and accompanies the screw in its motion. The lower die *l*, Fig. 2. is held in a box I, furnished with adjusting screws, which box is screwed down upon the bottom of the frame of the press, as is seen in Fig. 1. Now a piece of metal being placed on the upper die when the machinery moves the press, and forces the upper die down upon it, the tooth of the ring *d*, Fig. 5. obliges the die to turn with it, so that the coin is struck with a twisting motion, which is supposed to give a better impression; but in the recoil of the screw the die does not at first turn round, or it would inevitably cut away all the raised parts of the impression. This is effected by giving the tooth of the ring *d* considerable latitude in the opening made in the other ring for its reception, and this allows the screw to raise the die quite clear of the coin before it partakes of the twist of the screw.

The steel ring.

PLATE CCII. Fig. 2.

Fig. 3.

Fig. 4.

All the coins in this press are inclosed in a steel ring whilst they are struck, which method we believe was introduced by Mr Lawson, an agent of Mr Boulton, and now an officer in the mint. It is very ingeniously contrived to force out the money from it, which becomes jambed very fast into it by the expansion of the metal. The lower die *l*, as shewn in Fig. 2. is at top reduced to a neck only the size of the money it is to coin, and upon it is fitted the steel ring K, Fig. 3.; this slides freely up and down upon the neck of the die, but has always a tendency to rise up upon it by the action of a triple spring M surrounding the die beneath the ring. It is occasionally depressed by two levers *i i*, Fig. 4. affixed by centre pins to a ring N, which is fixed on the outside of the box I, Fig. 2. holding the lower die *l*. The inside ends of these levers *i i*, act upon the outside of the steel ring K, and the other ends are forked to admit chocks *m*, attached to the lower ends of the rods *h h*, and guided by the anterior edges of the frame, as shewn in Fig. 1.: these, by elevating the tails of the levers *i* whenever the screw rises, depress the opposite ends, and the ring with them. Then, suppose the screw at the highest point of its movement, the ring will be at the bottom, and its upper surface level with the surface of the lower die; now place a blank thereon, and when the screw of the press comes down, the rods descend with it, and the levers permit the springs M, beneath the ring K, to raise it up, and completely inclose the coin before the upper die comes upon it to strike the impression, which being done, and the screw beginning to return with the rods *h*, they elevate the tails of the levers, and thrust the ring down, leaving the coin loose upon the die, which being removed, and another blank placed upon it, the same operation is repeated.

Feeding mechanism.

Figs. 6, 7, 8.

PLATE CCII. Figs. 6, 7, 8.

The blanks are in this machine fed, or placed successively on the lower die by very ingenious mechanism, which is represented on an enlarged scale in Figs. 6, 7, and 8. Its connection with the press can be seen in Fig. 1. where *o n p* is a lever, moveable on a center *n*, and actuated at the upper end by a curved sector *o*, attached to the upper extremity of the screw *b*. This is so curved, that, in the reciprocating motion of the screw, the end of the lever moves alternately to and from the centre of the press. It is guided to move with steadiness, by fitting in a groove *r*. At the lower end it gives motion to a slider P, which carries the blanks singly from a tube, in which they are deposited, and lays them upon the lower die, then returns to fetch others. This slider is fitted in a brass frame or socket R, attached to the frame of the press. Thus, a piece of iron *r*, Fig. 1, is screwed to the check K of the press, with latitude for adjustment. To this the socket R is attached, by means shewn in Fig. 6. The projecting part *s* enters a notch in the upright side of *r*, Fig. 1, and by a centre pin is attached, like a joint, that it can swing round horizontally. The projecting leaf *t*, Fig. 6, embraces the opposite side of *r*, Fig. 1, and having a screw through it, fixes it fast, but admits of adjustment to make the slider carry the blank exactly to the right place. The socket R, Fig. 6, consists of two plates R and S. The projections *t* and *s* being part of the lower one S, and the upper one R is attached to it by screws and a leaf *v*, so that they are parallel to each other, but leave sufficient space between to receive the steel slider P, called the tongs. Q is a tube, into which the blanks are put, ten or a dozen at once, and are taken away one at a time by the tongs: These are shewn detached in Fig. 7. The principal piece is a ruler of steel *w*, to which the other piece *x* is connected by the joint *y*. The end forms a circular opening 1 for the reception of the blank, but will leave it when *x* is opened; 2 is a hook, which, when the tongs advance, enters a socket fixed behind the press; and this being adjustible by screws, ensures its leaving the blank in the exact position. The motion is given to the tongs by a frame of steel 3, Fig. 6. It slides in front of the socket RS, having a pin 4, which enters a fork in the lower end of the lever *o n p*, Fig. 1: It also extends beneath the lower brass plate S, and has three studs, or pins, which rise up from it, and passing through 3 grooves in the bottom plate S, reach the tongs *w*, and give them motion. This is shewn in Fig. 8, which is a plan of the sliding frame 3, 4; and 5, 6, 7 are 3 studs. The latter of these enters an opening *y*, Fig. 7, in the blade *w* of the tongs, where it has a small latitude of motion. The other two studs 5, 6 include the moving half *x* of the tongs between them, near the joint *y*, and act upon surfaces or edges thereof, which are inclined to the direction of motion for the tongs and slider. Its operation is thus: Suppose the tongs drawn back as far as they can be in this situation, the circular opening 1 in the tongs comes exactly beneath the tube Q, Fig. 6, and a blank falls down into the opening. Now, suppose the frame 3, 4 moved forward by the lever *o*, *n*, *p* acting upon the pin 4, its two studs 5, 6, which include the moving blade *x*, tend to shut the tongs up. This gripes upon the edge of the blank, and holds it fast between them whilst it advances, till it comes exactly over the lower die, to which position it is determined, and stopped by the hook 2 entering the socket before mentioned. In returning, the studs 5, 6 will evidently open the tongs before they communicate any motion to them, and will therefore leave the blank exactly where it was placed, and return empty to fetch another. It stops when it comes beneath the tube Q, and another blank falls into the opening 1; but the instant the advancing motion commences, the tongs close up, and hold it tight, as before mentioned. The lever *o*, *n*, *p*, Fig. 1, is made with a joint in it near the lower end, and is furnished with two springs, which act in the same manner as the springs in the back of a knife, to keep it straight, and carry the tongs forward; but if any obstruction arises, the lever bends, without forcing the tongs or slider forwards to break them. The centre *n* of the lever is adjustible to regulate the length of its motion by a sliding centre, which is fitted upon a vertical bar 9 attached to the frame.

Operation.

We have now described all the parts of this very ingenious machine; but it will be proper to say a few words on the manner of their action. The only attention the machine requires, is that of a little boy, who stands in a sunk place before the press, and always keeps the tube Q full of blanks. He has two strings, one of which will, when pulled, put the press in motion by the concealed mechanism in the room above, and by snatching the other string the press stops. Now, suppose the screw and upper die at the highest of their movement; the ball B of the fly, close to the end of the pole G; the lever *o*, *n*, *p*, and tongs P, in a contrary position to that of Fig. 1. viz. holding a blank exactly over the lower die; the ring forced down upon the neck of the die; in this state, by pulling one of the strings, the press starts the screw *b*, and the upper die begins to descend, the tongs open and then withdraw, leaving the blank upon the die. As the motion continues, the small levers *i*, *i* suffer the steel ring K to rise up by its springs M, and inclose the blank. Lastly, the upper die comes down, and strikes the coin with a twisting motion; the recoil and the concealed mechanism immediately causes its return; but the upper die does not partake of the twist of the screw, till the money is relieved. The tongs seize one of the blanks from the tube Q, and then carry it forwards, at the same time the small levers *i, i* depress the steel ring K, and leave the coin loose upon the die; then the end of the tongs, approaching with another blank, throw it forward into a box behind the press. The next stroke instantly succeeds, repeating the operation at the rate of 60 and 70 per minute, and that with very few interruptions for the whole day. The press room contains eight machines, all supported on the same stone base; and the iron beams EF between the columns, serve equally for the presses on each side: The whole has a very grand effect. The eight presses will strike more than 19,000 coins in an hour with only a child to supply each. The grand improvement in these presses consists, 1st, in the precision with which it operates to strike every coin with equal force, which could not be insured by the old press, worked by manual labour. 2d, The rising collar or steel ring in which they are struck, keeps them all of one size, and makes a fair edge, which the old coins never had, being rounded and defaced by the expansion of the metal under the blow. 3d, The twisting motion of the upper die is thought to produce a better surface to the flat parts of the coin, but of this there may be some doubt. 4th, The feeding mechanism is very complete, and allows the machine to work much quicker than in the old press, where the workman being in constant danger of having his fingers caught, was obliged to proceed cautiously, as well as to place the coin true on the die, which was however seldom done perfectly.

The want of feeding apparatus has been long felt as a great defect in the old coining press. In 1731, M. Du Buisson presented to the Royal Academy of Paris, a project for an apparatus to place the blanks upon the dies without depending upon the care of the workmen. It consisted of two sliders, one applied upon the other. The upper one had a hole in it for the reception of the money, the other was only a flat plate, to keep it from falling through. These sliders having taken a blank from a tube where they were deposited, were both advanced together by the movement of the press towards the die, and displacing the piece already struck from the lower die, laid the blank upon it, the lower slider proceeding no farther than the edge of the die. The whole contrivance was imperfect and awkward, but deserves to be recorded as perhaps the first attempt. See *Machines Approuvées par L'Academie*, 1731, vol. v. p. 155.

The feeding mechanism of Mr Boulton's press is also a French invention, as appears from a pamphlet entitled, *Rapport fait a la classe, des Sciences Mathematiques et Physiques, de L'Institut National; sur diverses Inventions de Jean Pierre Droz, relatives a L'Art du Monnoyage.* In this report a coining press, with the feeding apparatus like that which we have described, is minutely detailed, and also several other inventions which display much ingenuity; but they are not so complete as Mr Boulton's contrivances for the same purposes, who, by the application of his steam engine to put them in motion, as well as by several improvements in the making of the dies, has carried the art of coining to a degree of perfection hitherto unknown. (J. F.)

COIX, a genus of plants of the class Monœcia, and order Triandria. See BOTANY, p. 320.

COKE, SIR EDWARD, Lord Chief Justice of England, and one of the most distinguished lawyers whom his country has produced, was born of a good family, at his father's seat at Mileham in the county of Norfolk, in the year 1550.

A liberal course of education, according to the forms of discipline established at that period, contributed to bring to maturity those great talents, which were afterwards exerted, with so much benefit to his country, in the affairs of public life. At the age of ten, he was placed at the free-school at Norwich, whence he repaired to Trinity College, Cambridge, where he remained about four years. He then removed to Clifford's Inn, and, in the following year, was entered a student of the Inner Temple.

While in this situation, he already began to exhibit extraordinary proofs of his proficiency in the study of legal science, and of those acute powers of mind, for which, at a more mature age, he became so highly distinguished. These proofs of application and ability did not pass without observation and reward; for at six years standing, he was called to the bar; which was reckoned unusually early in those strict times. The first cause in which he appeared, in the court of Queen's Bench, was a remarkable action upon the statute *de scandalis magnatum*, in Trinity term 1578, which seems to have excited considerable interest, and of which he himself has given a judicious report. (See Rep. P. iv. fol. 12. b. 14. b.) About the same period, he was appointed Reader of Lyon's Inn; which situation he continued to fill during three years; and, by means of his lectures, which were much resorted to, he increased his reputation and his practice.

From this period he rose very rapidly in his profession; was chosen recorder of the cities of Coventry and Norwich; appeared in all the great causes which were tried in Westminster Hall; and was elected knight of the shire by the freeholders of Norfolk. He filled, successively, the offices of solicitor and attorney-general to the queen; and in the parliament held in the 35th year of Elizabeth, he had the honour of being chosen speaker. Towards the latter end of the reign of that princess, such was the degree of eminence to which he had attained, that he was constantly consulted by her majesty's ministers upon every matter of difficulty; and such was the estimation in which his talents and integrity were generally held, that, with his sanction, many measures, which might otherwise have appeared unusual and arbitrary, were rendered agreeable to the feelings of the people.

As attorney-general, he took a very active part in the conduct of the various and important state trials, which occurred in that and the succeeding reign. In the proceedings against the Earl of Essex, Sir Walter Raleigh, and the gun-powder traitors, he displayed uncommon vigilance, sagacity, legal knowledge, and oratorical powers; although in some of these, particularly during the trial of the unfortunate Raleigh, the lustre of his great talents was, in some measure, obscured by his intemperate behaviour and insulting language towards the accused, for which it were difficult to find an apology. In conducting the prosecutions instituted against the gun-powder conspirators, he exhibited an extraordinary degree of industry and acuteness; and with great ingenuity developed the origin, progress, and objects of that singular and nearly successful plot. His address to the jury in the trial of Garnet, one of the conspirators, was much admired at the time, and is still by many esteemed the masterpiece of this celebrated lawyer.

Although he enjoyed the highest reputation for learning and ability, Mr Coke does not appear to have courted admission to the presence of his sovereign, or to have solicited those honours and dignities to which his talents might have entitled him to aspire, with that avidity and impatience which are so usual among men who enter upon the career of public life. Upon the 22d of May 1603, however, when King James entertained the principal persons of the kingdom at Greenwich, on account of his quiet accession to the throne of England; Mr Coke, together with the Mayor and Recorder of London, received the honour of knighthood.

But higher dignities now flowed fast upon him. In consequence of his extraordinary exertions during the prosecutions above mentioned, he was called to the degree of a serjeant, on the 20th of June 1606; and on the last day of the same month, he was advanced to the situation of Chief Justice of the Common Pleas. This office Sir Edward filled, during several years, with ability and uprightness, and seemed desirous of retaining it; but, in consequence, it is believed, of some court intrigues, he was removed to the situation of Chief Justice of the King's Bench. Although, in this capacity, he evinced no great partiality for the unlimited prerogative of the crown; yet such was the favour he enjoyed from the king, and the expectations which were formed of the great services he was capable of rendering to the state, that, in the month of November 1613, he was sworn of his Majesty's Privy Council.

At this period, Bacon, the celebrated philosopher, was engaged in the pursuit of the same public honours, which the talents of Coke had already enabled him to attain. But the conduct of these two great rivals on the *arena* of public life was widely different. The upright mind of Coke disdained to employ any of those petty artifices, or to engage in any of those political intrigues, which are but too often resorted to as the most effectual means of advancement; and, trusting to his learning and abilities alone for distinction, it was his boast to have obtained the various offices, which he successively filled, "without either *begging* or *bribing*." Bacon, on the contrary, less impressed with a sense of the true dignity of human nature, than his scientific attainments might have led us to presume, did not hesitate to stoop to any means, however base and unjustifiable, by which he might raise himself to that station, which his genius and learning, had he relied solely upon them, would probably have procured for him in a more honourable manner. The avowed rival of Coke, he neglected no opportunity that occurred of attempting to diminish the respect which was universally paid to the talents and integrity of that great man, and to supplant him in the favour of those, in whom were the fountains of honour and reward. It affords an humiliating instance of the weakness of human nature, to behold genius and talents, which were calculated to grasp and embody the most important truths of science, thus prostituted to the meanest and most selfish purposes of personal elevation,—to see the mind of a Bacon exhausting and misapplying its energies on the paltry arts of political rivalry and court intrigue.

The pliant servility of Bacon prevailed over the ingenuous and manly virtue of Coke. Having succeeded, at length, in gaining entirely the ear of the king, he did not find much difficulty in procuring an opportunity of humbling his antagonist. In the course of the prosecutions which were carried on against the Earl and Countess of Somerset, and the other persons who were accessaries to the murder of Sir Thomas Overbury, the conduct of the Chief Justice, which appears to have been able, upright, and honourable, was misrepresented to the king and the people; the part which he took in the crown's cause of *Commendams*,* and in the discussion regarding the privileges of the Court of Chancery; and, above all, his unbending demeanour towards the favourite, Villiers, contributed gradually to deprive him of the royal favour; and the ultimate consequence was, that Sir Edward was suspended from the execution of his office, on the 30th of June 1616.

The talents of this able man, however, were too serviceable to the state to be long dispensed with; and accordingly we find that, a short while thereafter, he was restored, in some measure, to the favour of the king, and re-instated in his place as a privy-counsellor. It would appear, too, that the animosity of Bacon against him had at length relaxed; probably because he considered the friendship of Sir Edward as a necessary means of furthering his own ambitious views of aggrandisement.

From this period he was engaged in many important affairs of state, and the greatest deference was paid to his opinion upon every measure of policy which the crown proposed to adopt. In the year 1620, the king's affairs appeared to be in such a state of embarrassment, as absolutely required the calling of a parliament; at least, this measure was strongly advised by the Lord Chancellor Bacon, after consulting with Sir Edward Coke. The conduct of Sir Edward, however, proved very different from what the court and the favourite, Buckingham, had expected; and, instead of becoming a mere tool in the hands of the ministry, he shewed himself, upon every occasion, to be a steady and patriotic friend to the liberties of his country. In consequence of the freedom and boldness with which he opposed the illegal pretensions of the crown in Parliament; he was, on the 27th December 1621, committed to the Tower; while, at the same time, his chambers in the Temple were broken open, and his papers taken out and delivered to certain persons to be examined. On the 6th of January, 1622, Sir Edward was charged before the council with having concealed some true examinations, in the great cause of the Earl of Somerset, and substituting false ones in their place. This charge, however, was not followed up by any proceedings against him, and does not, indeed, appear to have had any real foundation; for he was soon afterwards released from confinement; but the king thought proper, for the second time, to strike him off the list of privy counsellors. Towards the close of the year 1623, we find his name joined with several others, in a commission issued by the king relative to the affairs of Ireland; but this might be considered rather as a species of honourable banishment, than as a mark of the royal favour and confidence; and it does not appear that he ever left the kingdom.

During the remainder of King James's reign, Sir Edward continued to adhere firmly to his principles and opinions; nor is there any appearance of his having again attempted a reconciliation with the court. In the parliament which was held in the year 1628, he was chosen knight of the shire for the county of Bucks, and

---

* The question was put to the judges: "*Whether, in a case where the king believed his prerogative or interest concerned, and requires the judges to attend him for their advice; whether, in such a case, they ought not to stay proceedings till his Majesty has consulted them?*"

All the judges submitted to the affirmative side of the question, excepting Coke, chief justice of the King's Bench, who said, "*That when the case happened, he would do his duty.*"

Coke.

greatly distinguished himself by the strenuous support which he gave to all questions favourable to the liberty of the subject, and the privileges of the commons. He took a most active part in all the important discussions which occupied the attention of this parliament, and had the principal share in proposing and framing the famous *Petition of Rights*. On the 5th of June of the same year, he vindicated the right of the House of Commons to proceed against any subject, how exalted soever he might be, and expressly denounced the Duke of Buckingham as the "grievance of grievances," and the great cause of all the calamities of the country.

But the active and useful life of this distinguished statesman was now drawing towards a conclusion. After the dissolution of this parliament, on the 28th of March 1628-9, he retired to his house at Stoke-Pogey's in Buckinghamshire, where he spent the remainder of his days in a state of seclusion from public life. He died there, on the 3d of September 1634, in the eighty-sixth year of his age.

The person of Sir Edward Coke was well proportioned, his features regular, his countenance grave, and his manner dignified. In his dress he was always neat, without foppery or ostentation; and it was a saying of his, "that the cleanness of a man's clothes ought to put him in mind of keeping all clean within." His mind was active, vigorous, and penetrating; his memory retentive, and his judgment solid. Strength and conciseness formed the general characteristics of his legal pleadings; but in his writings and set speeches he adopted rather a diffuse style; which may have proceeded partly from the redundancy of his learning, and partly from the quaint manner of the times in which he lived. He appears to have possessed all the qualities which are requisite to form a great lawyer; and no man ever studied the laws and customs of his country with greater zeal, assiduity, and success, or displayed more acuteness in tracing the principles upon which they are founded. As a judge, he enjoyed the highest character for talents, learning, and integrity; and there are few men whose lives have been more entirely and sincerely devoted to the service of their country, and to the maintenance of its constitution. As a servant of the crown, he was zealous and faithful; and while he supported the just prerogative of the executive, he did not hesitate to oppose any attempts to stretch it beyond the legal and constitutional bounds.

During the course of his public life, he experienced many changes of fortune; but in every situation he preserved the same composure of mind and consistency of conduct: thus verifying the prediction of King James, who is reported to have said of him, "that which ever way he was thrown, he would fall upon his feet." When removed from his office of chief-justice, there is reason to believe, that he might have retained his situation had he shewn sufficient compliance with the wishes of the court; but when such an overture was made to him, his answer was, "that as a judge ought not to *take*, neither ought he to *give* a bribe," nobly preferring the loss of office and emolument to the prostitution of his talents. He is said, indeed, to have valued himself chiefly upon having obtained all his steps of preferment, "without employing either prayers or pence." Towards the latter part of his life, although connected by various ties with the persons in power, he devoted himself zealously and steadily to the service of the people, and exerted his talents, upon every occasion, in the defence of their rights and liberties, against the arbitrary encroachments of the crown.

Sir Edward was twice married. His first wife was Bridget, daughter and co-heiress of John Paxton, Esq. with whom he acquired a considerable fortune, and by whom he had seven sons and three daughters. By his second wife, Elizabeth, daughter to Thomas, Earl of Exeter, he had two daughters.

Colbert.

Although he was constantly engaged in the active business of life, he yet found leisure to compile several laborious and highly valuable works, illustrative of the laws and constitution of his country. These are,

1. His Reports of Cases and Matters in Law; in thirteen parts: Of which eleven were published by himself, the other two having appeared after his death. These reports are so highly esteemed, that they are generally cited without the author's name.

2. A "Book of Entries, containing perfect and approved precedents of Counts, Declarations," &c. Fol. 1614.

3. His "Institutes," in four parts; the first of which contains a comment upon Littleton's treatise of tenures; the second, a comment upon *magna charta*, and several other ancient acts of parliament; the third, a treatise of the pleas of the crown; and the fourth, an account of the several courts of the kingdom.

4. "A Treatise of Bail and Mainprize." London, 1637, 4to.

5. "Reading on the Stat. of Fines." London, 1662, 4to.

6. "Complete Copyholder." London, 1640, 4to.

See *Biographia Britannica*, vol. ii. (*z*)

COLBERT, John Baptiste, Marquis Sagnelai, an eminent statesman of France, whose family was originally from Scotland, was born at Rheims, in 1619. He displayed, at a very early age, an uncommon partiality for commercial and financial speculations. He read with avidity all the ablest works on these favourite subjects, and made a tour through the provinces of France, with a view of acquiring an accurate knowledge of the state of its manufactures and its trade. His distinguished talents as a financier procured him the favour of the Cardinal Mazarine, who honoured him with his unlimited confidence, entrusted to his management the most important concerns, and during his last illness, not only appointed him one of the executors to his will, but recommended him to his sovereign, as a person entitled, by his worth and qualifications, to the highest offices in the state. In compliance with the recommendation of his distinguished minister, Louis XIV. appointed Colbert intendant of the finances. His exertions, in this important situation, were highly judicious and beneficial. By abolishing those useless places, which had been created, not for public utility, but to favour individuals, by restoring order in the receipts and payments of the exchequer, and by a rigid regard to economy, he materially improved the treasury, while he diminished the load of taxes which his predecessors had imposed upon the people. He effected another equally important, and more difficult reformation, by establishing a court of justice to examine and decide on all financial concerns. By means of this court he recovered many alienations of the revenue, and suppressed many unjustly acquired annuities, the original of which he caused to be repaid. Nor was he was less active as superintendant of the public buildings, to which situation he was appointed in 1664. Ambitious to give to the palaces and buildings of Paris a splendour suitable to the grandeur of the French monarchy, he invited from all the countries of Europe architects, sculptors, and other artists of distinguished eminence, whom he employed on the most liberal terms, in their embellishment. His principal attention, however, was occupied by the grander project of promoting the commercial importance of his country. As a preparatory step to the completion of his magnificent designs, he increased the royal navy far beyond its former strength; and having thus secured protection for future adventurers in trade, he determined, notwithstanding all the misfortunes and failures of his predecessors, to revive the French East India Company. For this purpose it was necessary, not only to acquire an accurate and comprehensive knowledge of every thing requisite to ensure the success of his project, but to give a new impulse to the public mind, discouraged by so many disappointments. Having procured, therefore, the necessary information from those mercantile people who were most conversant with East India affairs, he employed the pens of the most able academicians to explain and recommend his views, and thus to engage the hopes and energies of the nation in their promotion. By these exertions he completely succeeded, and had the honour of accomplishing an object which had baffled the most strenuous efforts, and disappointed the most sanguine hopes of some of the ablest politicians of France. The establishment of the East India Company, was followed by that of the West India and African Companies, from which many important advantages accrued to his country. While thus occupied in the extension of its commerce, he did not overlook its internal manufactures: and scarcely a year of his ministry passed without the introduction of some new manufacture, or of some improvement in those previously established, to employ the industry of his countrymen, and to ameliorate their condition. Perhaps nothing contributed more essentially to these important ends, than the grand canal of Languedoc, by which he united the two seas that bound the opposite coasts of France. This magnificent undertaking, which was completed in fourteen years, will entitle Colbert to the perpetual gratitude of the French nation. By his zealous encouragement of literature and the arts, he has established as indisputable a claim to the gratitude and admiration of the learned in every country, and to the latest posterity. He established the French academy of painting; the institution of the academy of science was owing in a great measure to his patronage and his exertions; and the academy of inscriptions took its rise from an assembly of some literati in his house for the purpose of furnishing designs for the king's medals. On the theological student he has conferred an important favour, by the collection of those manuscripts of the Greek Testament, which are known by the name of *Codices Colbertini*, and are now in the royal library of Paris. Five of these MSS. containing the four gospels, of which two are referred to the 11th century, were collated by Simon, and their readings noted in the margin of Curcellæus's edition of the Greek Testament. Mills, in his edition of the Greek Testament, has given a variety of readings from seven other Colbert MSS; made very superficially by Larroque, and communicated by Alix. One of these, divided by Mill into three separate MSS. contains the whole New Testament, except the book of Revelation, and was supposed, in Mill's time, to be 600 years old. Griesbach, in his Symbolæ, defends this MS. against the suspicion of its having been altered from the Latin, assures us that its readings harmonize with those of Origen, refers it to the eleventh or twelfth century, and esteems it a MS. of great value. Wetstein collated, in 1715, twelve other *Codices Colbertini*, which are merely lectionaria of the four gospels.

Colbert, after a life of extensive usefulness, and after having filled many important situations in the state, died in September 1683, in the 65th year of his age, leaving behind him few equals for uncorrupted integrity, grand views, and extensive knowledge as a politician, with a zeal and perseverance before which the most formidable obstacles were compelled to yield. See Voltaire's *Age of Louis XIV. Histoire de France. Univ. Hist. Nouvelle Dictionaire Historique.* For an account of the *Codices Colbertini*, the reader may consult, *Bibliotheca Colbertina*, Parisiis, 1728; Montfaucon's *Bibliotheearum*, tom. ii.; the second volume of the *Catalogue MSS. Bibliothecæ Regiæ*; and Michaelis's *Introduction to the New Testament* by Marsh, vol ii. iii. (*k*)

COLCHESTER, a town of England, in the county of Essex, is situated on the banks of the navigable river Colne, on the top and northern side of a gentle eminence. The river, which is crossed by three bridges, flows on the north and east sides of the town. Although the greatest care was taken to preserve the ancient walls which surrounded the town, and consisted of stone and Roman brick, yet they are now in a great measure destroyed. When the walls were perfect, they enclosed an area of 108 acres, and the town was entered by four principal gates and three posterns. Several bastions, and an old Roman fort, contributed to the strength of the town, and deep ditches were cut where the defences were weakest. The part of the town with the out walls is extremely irregular. The principal street, which stretches due east and west, is adorned with several elegant houses and shops, but is broken by the intervention of the old market-house and other small buildings.

Upon an eminence, called the Bailey, in the centre of the town, to the north of the high street, stand the venerable ruins of the castle, built by Edward, son of Alfred the Great. The outer walls of the keep, which are remarkably thick and solid, are nearly perfect, and, like the rest of the building, seem to be constructed of stone, flint, and brick. The principal public buildings in Colchester, are the Baize-hall, where the goodness of the baize manufacture is tried by a corporation; the Guild-hall, called also the Moot-hall, built by Eudo; the town gaol; the work-house; the theatre; the free grammar school; the barracks, for cavalry and infantry; the public churches; the ruins of St John's Abbey, and St Botolph's Priory; and several charity-schools, and almshouses.

St John's Abbey, which was a very magnificent building, was founded in 1097 by Eudo Dapifer; but very little more than the entrance gateway, built with hewn stone and flint, now remains. The construction of the abbey church was singular, having a central tower with circular angles terminated by small spires of a conical form. The priory church, which contains some interesting specimens of interlacing arches and brick ornaments, was almost demolished during the civil wars. The original length of the building within the walls was 108 feet, and its breadth, including the nave and aisles, 44 feet. St Mary Magdalen's hospital was founded for persons afflicted with leprosy. It consists of a few old buildings to the north of St Magdalen's church. The principal churches are St James's, founded about the reign of Edward II. and consisting of a body chancel and side aisles, with a square tower at the west end; All Saints church, built before 1356, and having its tower chiefly of flint, with some stone work at the angles; St Nicholas's church, which is partly in ruins, the tower having fallen in through the body and chancel some years ago; Trinity church, which contains a monument to the famous Dr Gilbert, the founder of the science of magnetism; St Martin's, erected about the year 1327, which is now in ruins, and has its tower partly composed of Roman brick; St Peter's, founded previous to the conquest; and St Mary's, which stands in an elevated situation, near the south-west corner of the town, and which had its main tower raised 12 feet, was repaired in 1729.

The river Colne is navigable for large vessels within three miles of the town, and up to the Hythe it is capable of receiving brigs and small vessels which come close to the houses, where there is an extensive quay and custom house. The principal articles of manufacture are, baize, say, serges, and some other woollen articles, which give employment to the inhabitants in the town and its vicinity. About 100 looms are employed in silk goods, and a considerable trade is carried on by means of the oyster fishing, the Colchester oysters being in great demand.

The following is the population of this town in 1811:

Number of inhabited houses, ...	2111
Number of families that occupy them, . . .	3093
Uninhabited houses, ...	57
Families chiefly employed in agriculture, . .	480
Families chiefly employed in trade, &c. . .	1152
Males, ...	5400
Females, ...	7144
Total population, ...	12544

For a full account of the history and antiquities of Colchester, see Morant's *History of Essex*, vol. I.; *Philosophical Transactions*, Aug. 1699; *The History and description of Colchester*, 1803; and Brayley and Britton's *Beauties of England and Wales*, vol. v. p. 286. (*o*)

COLCHICUM, a genus of plants of the class Hexandria, and order Monogynia. See BOTANY.

COLCHIS, or COLCHOS, now *Mingrelia*, was an ancient kingdom of Asia, bounded on the east by Iberia, on the south by Armenia and Pontus, on the west by the Euxine Sea, and on the north by Mount Caucasus. Its principal rivers, all of which disembogue themselves into the Euxine, are the Ophis, the Cissa, the Phasis, the Cyaneus, the Absarus, the Charistus, the Hypus, and the Corax. Its cities, which deserve notice, were Aca, the metropolis of the dynasty; Pitynus, now Pitchinda; Dioscurias; and Cyta, formerly Cuta, the birth-place of Medea. The whole region, though remarkable for the number of its poisonous herbs, which perhaps gave to its honey that bitter flavour which it is said to have possessed, was exceedingly fruitful in every necessary that could administer to the comfort of its inhabitants; and as it abounded in flax, hemp, wax, pitch, and timber, it was not only well adapted, by means of the rivers which intersected it, for internal traffic, but likewise to carry on an extensive foreign trade by navigating the Euxine. Hence, along the shores of this sea, the Colchians established many settlements, which served as marts for their various articles of commerce; and to which they exported, not only the raw productions of the country, but also the goods which they manufactured, especially linens, which they carried to a great degree of perfection. They were no less famous for the exquisite figures of flowers and animals with which they variegated their cloths; and for the beauty and durability of their colours, which no washing or length of time could efface. We may add, that the mines of gold, which enriched this territory, are said to have given occasion to the voyage of the Argonauts, which we formerly described, and which became the subject of some of the most pathetic strains which ever flowed from the romantic Muses of Greece and Rome.

The most probable conjecture concerning the first inhabitants of Colchis, is, that they were a branch of the Cuthites, who, in the most remote antiquity, emigrated from their native country in Arabia, and settled there. Hence, though they were not the real descendants of Mizraim, who peopled Egypt, as has been generally thought, they were undoubtedly a kindred race, and bore a striking resemblance to them. Herodotus, not to mention Diodorus, Apollonius, Strabo, &c. who appear to have copied him, asserts that the Colchians resembled the Egyptians in their form and features; in their woolly hair and dark complexion; in their language, laws, and manners; in their manufactures and commerce. Nor can we omit, that this region, before its name degenerated into Colchis, was denominated Cuteis, or Cutais; and one of its chief cities, Cuta, or Cutaia; appellations, in all probability, derived from Cush, the founder of the Cuthites. From Herodotus we likewise learn, that long after this emigration, Sesostris, king of Egypt, when warring with the Scythians, left a part of his army in Colchis to defend the passes, who settled in that region; and that colonies of the Ampreutæ, the Lazi, the Heniochi, the Istri, the Marsi, the Moschi, and the Manralæ, from the last of whom some deduce the name of Mingrelia, at different periods, increased the original inhabitants of the country.

That Colchis was at first governed by independent princes, must be admitted, but their names and exploits have not descended to our times. Œetes swayed the sceptre, when the Argonauts landed upon his shores, and deprived him of the golden fleece, and the beautiful Medea. At his death, according to Strabo, the kingdom was divided into several petty dynasties; but we find it again united in the time of Xenophon, who informs us, that when he penetrated, under Cyrus, into Asia, a descendant of Œetes, who bore the same name, reigned there. Mithridates the Great, in his first career of victory, overran the country; but when he was forced to yield to the superior destiny of Rome, the Colchians again asserted their freedom. Peace being obtained from Sylla, Mithridates led his forces to take vengeance on the Colchians, who, afraid of his arms, offered to receive his son, who bore the name of his father, as their king, provided that the independence of the crown should be acknowledged. The king of Pontus seemingly agreed to this request, and the Colchians laid down their arms; but the haughty soul of the invader cherished in secret a deep-rooted resentment, not only against the state who made the proposal, but against the son, who seemed to be preferred to himself. When the young prince was about to take possession of his kingdom, his father, yielding to the dictates of jealousy and ambition, loaded him with fetters of gold, and at last put him to death. The spirit of the Colchians, roused at this unworthy treatment, set at defiance the power of Mithridates, which he led to subdue them; but his army, which he conducted through the hostile territory of the Achæans, a people situated on the eastern shore of the Euxine, was almost annihilated by the ambushes of the inhabitants and the rigours of the climate; and the Colchians were delivered from his arms. Olthaces, who afterwards mounted the throne of Colchis, entered, however, into an alliance with Mithridates, in a subsequent war with the Romans; but his forces yielded to the legions of Pompey, who took him prisoner, and led him in triumph. As the reward of services rendered to Pompey in that war, the Roman general raised one Aristarchus to the throne of Colchis. His reign, however, seems to have been but short; for Pharnaces II. son of Mithridates, soon after subdued the kingdom of Colchis, whilst Cæsar was wasting his time in the embraces of Cleopatra; but when that leader again returned to the field, the conqueror of Colchis lost the fruits of his victory. Our attention is not again called to the Colchians, till the reign of Trajan, to whom they willingly submitted. It is probable, that the king which they had at this time, was allowed to reign in subjection to the Romans; but the country was soon deprived of this shadow of royalty, and without being even formed into a province by any of the emperors, it fell under the jurisdiction of the Prætors of Bithynia and Pontus. We shall only add, that Colchis shared in the fortunes of the eastern empire, when it was overturned by its barbarous invaders, and now forms a province of Asiatic Turkey. (N)

COLD.

Definition.

COLD, is a peculiar sensation excited in animals, when substances at an inferior temperature are applied to their organs of feeling. It is also used to denote a certain principle or power residing in bodies, by the operation of which the sensation is produced. It is still doubtful, whether this principle ought to be regarded as a distinct condition of matter, or as a mere modification of caloric; though we are disposed to consider it in the latter point of view.

The means, with which we are acquainted, of reducing the temperature of bodies, are much more limited in their effects, than those of increasing it. But many important facts connected with the production of cold have already been discovered; and though we can scarcely expect ever to acquire the same extensive command over the lower, as we already possess over the higher temperatures, we have reason to hope, that since we know the circumstances upon which refrigeration depends, processes of cooling may yet be discovered still more effectual than any that have hitherto been employed.

The various methods of producing cold, which are at present known, may all be referred to Rarefaction, Evaporation, and Liquefaction, induced by chemical action. We shall consider, in order, each of these methods of reducing the temperature of bodies.

Production of cold by rarefaction.

If an aërial fluid be suddenly enlarged in volume, by the removal of any mechanical pressure to which it may have been subjected, its temperature is perceptibly diminished. Thus, a thermometer exposed to the stream of air which issues from an air-gun, has its temperature reduced 5 or 6 degrees; and a similar effect is produced when it is inclosed in the receiver of an air pump, during the process of exhaustion. The diminution of temperature by rarefaction, is well exemplified by the celebrated fountain of Hiero, at the mines of Chemnitz in Hungary, where the air in a large receiver is compressed by a column of water, equal to the weight of about 8 atmospheres. On turning a stop-cock, the air suddenly makes its escape, and during its expansion, deposits the watery vapour which it held in solution, in the form of snow, or covers the inside of the tube through which it rushes, with slender spiculæ of ice. In most cases, however, this method of producing cold is very limited, and scarcely capable of being applied to practical purposes.

Production of cold by evaporation.

Evaporation is of more extensive influence in reducing the temperature of bodies, than rarefaction. Every person must have felt, that when the hand has been dipt in water and then exposed to a current of air, the parts which had been moistened soon became much colder than the parts which had been allowed to remain dry, though the cooling medium is the same. Dr Cullen appears to have been the first who ascribed the difference of effect to the evaporation of the fluid. He observed, that a thermometer, the bulb of which had been dipt in a fluid, and then exposed to a current of air, always indicated, so long as it remained moistened, a lower temperature than the air itself; and that the reduction of temperature was greatest when the thermometer had been dipt in the most volatile fluids. If the bulb of the instrument be surrounded with a piece of linen well moistened with ether, and afterwards exposed to a free current of air, the temperature is reduced from 50° to near zero. The effect with alcohol is considerably less, and with water it is limited to four or five degrees. Water may, in this manner, be frozen, by pouring a small quantity of it into a slender tube which is surrounded with linen moistened in ether, and then swinging the tube rapidly round the head by means of a string attached to it.

Freezing of water by the evaporation of ether in the open air.

When water is made to ooze slowly through porous unglazed earthen vessels, it presents a very extensive surface to the atmosphere, and as it suffers a proportional degree of evaporation, its temperature is kept considerably below that of the air. If one of these porous vessels be allowed to imbibe water for some time, it retains, when the water is poured out of it, a considerable quantity of moisture; and as it now presents both an internal and an external surface to the air, the evaporation is greatly increased. The absorption of caloric for the conversion of the water into vapour is increased in an equal degree, and consequently a greater reduction of temperature is obtained. Accordingly, liquors are very conveniently cooled, by placing the bottles which contain them, in these unglazed earthen vessels, previously well moistened with water. Wet cloths wrapped round bottles produce the same effect. In India, where the conversion of water into ice is the sole employment of many individuals, the water to be frozen is exposed during the night in flat unglazed earthen vessels, which are placed upon the worst conductors that can be procured, such as sugar canes, dried stems of maize, &c. The dryness of the air causes a very considerable evaporation, and the consequent reduction of temperature is such, that a thin film of ice is formed towards the morning, though the temperature of the air may have been all the time above the freezing point. The quantity of ice obtained is greater when the weather is warm and dry, than when it is moist, though in the latter case the temperature of the air may have been actually lower.

Method of procuring ice in India.

As liquids assume the state of vapour, at a very reduced temperature, when the pressure of the atmosphere is removed from their surface, it might be expected, that a more rapid as well as a greater production of cold would be obtained by inclosing them in the receiver of an air-pump, and then exhausting the air. Accordingly, if a small tube, about a quarter of an inch in diameter, and four or five inches long, be nearly filled with water, and

Freezing of water by the evaporation of ether under an exhausted receiver.

then placed in a beer glass containing about a cubic inch of ether; if in this state, the whole be included in the receiver of an air-pump, and the air be exhausted slowly and gently, the ether will pass into a violent ebullition, and soon be converted into vapour. But in order to undergo that change of condition, the ether must derive the necessary supply of caloric, either from itself, or the contiguous bodies. This abstraction of caloric soon reduces the temperature of the ether, and that of the bodies in contact with it; and at length a degree of cold is produced sufficient to freeze the water inclosed in the tube. It is necessary, however, to continue the process of exhaustion during the whole of the experiment, otherwise the vapour of the ether would soon act by its elasticity on the surface of the liquid part of it, and produce the same mechanical effect as the atmosphere.

Freezing of water by its own evaporation under an exhausted receiver.

Mr Leslie has suggested a beautiful variety of this experiment. It occurred to him, that, by a sufficient degree of exhaustion, water itself might be converted into vapour at the ordinary temperature of the atmosphere; and that the quantity of caloric necessary for that purpose being abstracted from the water, might reduce its temperature so much as to cause it to freeze. In order to supersede the necessity of removing the vapour by continued exhaustion, he inclosed a quantity of highly concentrated sulphuric acid under the same receiver with the water subjected to experiment, in a separate vessel. The acid, by its strong attraction for humidity, absorbed the vapour of the water as fast as it was disengaged, and thus left the vacuum as complete as before, while the water, by being gradually deprived of its caloric, was at last reduced to the freezing point, and passed into the state of ice. We shall state, very briefly, the circumstances to be attended to in performing this very interesting experiment. The air-pump must possess an exhausting power, capable of bringing the gage within at least half an inch of the barometrical column; the sulphuric acid should be highly concentrated, and should present as large a surface as the receiver will allow, for absorbing the vapour as rapidly as possible. The cup for holding the water, should be made of unglazed earthen ware, very flat, and placed at such a distance from the sulphuric acid, as not to be affected in any great degree by the increase of temperature which it suffers from absorbing the vapour. And lastly, the receiver should not be larger than is barely sufficient for containing the apparatus for the experiment.

Arrangement of the apparatus.

The vessels for containing the water and the sulphuric acid, are disposed in the following manner: The cup which contains the acid is placed on the plate of the air-pump, and a flat vessel of the shape of a beer-glass is then placed in it, to support the porous cup which contains the water, and keep it at a sufficient distance from the acid. By this arrangement, the cup containing the water is protected from any radiation that might take place from the sulphuric acid, while the glass, being a bad conductor, suffers very little heat to be conveyed by transmission. Instead of sulphuric acid, any other substance that has a strong attraction for humidity may be employed, as dry potash, muriate of lime, &c. though sulphuric acid, when it is highly concentrated, appears to answer the purpose best. We have indeed, determined by experiment, that when equal weights of sulphuric acid, and various deliquescent salts, are placed under a receiver, and the air exhausted, the sulphuric acid abstracts moisture from all of them which we have tried.

If the air-pump be good, and the sulphuric acid sufficiently concentrated, the congelation of the water generally takes place in two minutes, even when the temperature of the room is 50° or 60° of Fahrenheit's scale. We have had an opportunity of performing the experiment with a very powerful air-pump, constructed by Miller and Adie, which brings the gage to within $\frac{1}{10}$ of an inch of the barometrical column, and have sometimes succeeded in *a minute and a half* from the commencement of the exhaustion, though the temperature of the water was then 60°. When the exhaustion is nearly completed, the water is thrown into a state of violent ebullition, and occasionally large bubbles are arrested before they have time to burst, and suddenly converted into thin hemispheres of ice. At other times, if the exhaustion be less perfect, and carried on without exposing the water to much agitation, the temperature is frequently reduced 10° below the freezing point without congelation taking place; but upon giving a sudden blow to the air-pump, and thus communicating a tremulous motion to the apparatus, the water is instantly frozen, while the temperature starts up to 32°.

We may determine by an approximated calculation, how much of the water must be evaporated, to reduce it from some given temperature to the freezing point. Thus let the temperature of the water at the commencement of the experiment be 50°: since water, in its transition to vapour, absorbs as much caloric, as in a sensible state would raise its temperature about 900°, in order that it may be reduced 18°, or from 50° to 32°, a quantity of the whole must be evaporated equal to $\frac{18}{900}$, or $\frac{1}{50}$.

The same experiment performed by means of the vacuum procured by steam.

We have succeeded in performing the experiment of Mr Leslie, with the partial vacuum procured by steam. The boiler we employed for the purpose was pretty large, and had an iron lid soldered to it, in the middle of which was a stop-cock, having an internal screw adapted to the external screw of another stop-cock. The latter was affixed to the under side of a brass plate, which was intended to support the receiver and the freezing apparatus. The boiler was placed on a brisk fire, with a little water in it, and the stop-cock was left open, to allow the air to escape. After the water had boiled a sufficient time to expel the air, the stop-cock was turned, and at the same instant the boiler was removed from the fire, and plunged into a vessel of cold water. When the steam was sufficiently condensed, the brass plate with its apparatus was screwed to the stop-cock of the boiler, a collar of leather being interposed between the screws, to make the junction air tight. The stop-cock of the boiler was then turned, and a communication being thus opened between the receiver and the boiler, the air rushed by its elasticity from the latter to the former, and produced a partial vacuum in the receiver. The stop-cock connected with the plate was then turned, and unscrewed from the stop-cock of the boiler. The process of expelling the air from the boiler by steam was repeated, and after the vapour was condensed, a communication was again opened as before between the receiver and the exhausted boiler. This was repeated, until the exhaustion of the air in the receiver was sufficiently great for the success of the experiment. When the receiver was small, three or four times were sufficient.

We are disposed to think, that this experiment might also be repeated very conveniently, by means of a Torricellian vacuum obtained by water.

Freezing of mercury by the evaporation of ice under an exhausted receiver.

As it was well known that ice suffered a gradual diminution by evaporation, even when the temperature was considerably below the freezing point, Mr Leslie concluded, that this evaporation would go on still more rapidly *in vacuo*, and that a great reduction of temperature would be obtained, by placing a quantity of ice under a receiver, in circumstances similar to those we have already described, and then exhausting the air. He therefore attempted to freeze mercury, by incrusting the bulb of a thermometer with a thin coating of ice, and then exposing it in that state over a cup of sulphuric acid, under an exhausted receiver; but the experiment was unsuccessful; for, though the reduction of temperature was considerable, the mercury, owing to the imperfection of the air-pump, was not frozen. Soon after, however, he had an opportunity of trying the experiment a second time, with the very excellent air-pump constructed by Miller and Adie already mentioned, when he had the high gratification of realizing his conjecture, and seeing the mercury in the bulb of the thermometer partially congeal. For the sake of those who may wish to attempt this very beautiful experiment, we may mention, that the air-pump should be sufficiently powerful to bring the gage within $\frac{1}{15}$th of an inch at least of the barometrical column, at the time of the experiment; and that the sulphuric acid employed for absorbing the vapour of the ice, should be in the most concentrated state in which it can be procured. The crust of ice which enveloped the bulb of the thermometer in this experiment of Mr Leslie, was attached to it, by suspending the instrument from a rod, which passed through a collar of leather on the top of a receiver, and then alternately immersing the bulb in a cup of water, and exposing it, in circumstances already mentioned, to the cooling influence of evaporation in a partial vacuum. The cup of water was placed immediately under the bulb for the conveniency of the immersions, and removed from the receiver when the crust of ice on the bulb was sufficiently thick. The bulb with its coat of ice was then suspended about an inch above the cup containing the sulphuric acid, and the receiver was exhausted, until the gage was brought to within $\frac{1}{30}$th of an inch of the height of the barometrical column, at the time of the experiment. After the experiment had been allowed to proceed during half an hour, a sudden contraction was observed in the mercury; the air was re-admitted, and the thermometer being withdrawn as quickly as possible, it was found, on breaking the bulb, that a small portion of the mercury was actually in a solid state.

We have performed this experiment with the same air pump, by arranging the apparatus a little differently, and with a more decisive result, as the congelation of the mercury was more rapid and complete. The principal difficulty in Mr Leslie's mode of performing the experiment, is experienced in giving the coating of ice to the thermometrical bulb. We avoided this, by taking a lump of solid ice, and giving it, by means of a piece of hot iron, the shape of a cup about $\frac{1}{8}$th of an inch thick. This cup was suspended in net-work, about an inch above the sulphuric acid. The mercury to be frozen, which was previously reduced to 32°, to prevent it from melting the bottom of the cup, was poured into it, and then covered with a shallow stratum of water, about the same depth as the thickness of the cup. The whole was covered with a receiver, and the air was exhausted as quickly as possible. The water above the mercury was immediately frozen, so that the mercury was completely enveloped in ice, and in contact with it. The air of the room was about 60°, and the gage was brought within $\frac{1}{15}$th of an inch of the height of the barometrical column. In about 3 minutes, the ice began to exhibit an evident appearance of a rapid waste by evaporation, its surface becoming rugged and uneven. It then cracked in several places and discovered part of the mercury, which seemed to be in the solid state. At the end of 6 minutes, the air was re-admitted, and the cup of ice being taken out of the receiver and broken, the mercury was found to be completely solid. It sustained repeated blows of a hammer, and appeared to possess an imperfect degree of malleability. A part of it being thrown into water, was immediately surrounded with a shell of ice.

Production of cold by liquefaction.

The third method of producing cold which we proposed to consider, is liquefaction induced by chemical action. We have already explained (see CHEMISTRY, page 42) the general principles upon which the reduction of temperature by liquefaction depends. We shall now give a more detailed and practical view of the subject.

The solution of salts in water, by the transition to the fluid state, is always accompanied with a considerable diminution of temperature. When nitre is added to water, at the ordinary temperature of the atmosphere, until the water is saturated, the temperature is reduced 15 or 16 degrees; and a still greater degree of cold is obtained by the solution of muriate of ammonia. But of all the salts, nitrate of ammonia seems to undergo the greatest reduction of temperature during its solution. If it be mixed, in the state of a fine powder, with an equal weight of water, the temperature is reduced from 50° to 4°.

Solution of salts in water.

The greatest number of experiments on this subject, have been made by Mr Walker of Oxford. Being aware that water, saturated with one salt, was still capable of dissolving a portion of another, he inferred, that a greater reduction of temperature would be obtained, by dissolving different salts in succession, than by the solution of any one of them separately. The conjecture was confirmed by experiment. We have already mentioned, that nitrate of ammonia being dissolved in an equal weight of water, reduces the temperature of the ingredients from 50° to 4°; but if an equal weight of carbonate of soda be added, the temperature is reduced from 50° to 7°, though the latter salt, when employed alone with water, has but little frigorific effect.

Solution of salts in acids.

As the production of cold, by freezing mixtures, depends partly upon the rapidity with which the substances employed pass into the liquid state, and partly upon the increase of capacity for caloric which is acquired by that transition, it might be expected that a greater reduction of temperature would be obtained, by dissolving salts in acids than in water. Accordingly, by dissolving a pound and a half avoirdupois of Glauber's salts (sulphate of soda) in 12 ounces of nitrous acid, previously diluted with 6 ounces of water, Mr Walker obtained a diminution of temperature from 50° to —1°; when sulphuric acid, diluted in the same proportion, was employed, the reduction was from 50° to 5°; and three parts of the same salt by weight reduced to a fine powder, and dissolved in two parts of muriatic acid, sunk the thermometer from 50° to zero. The reduction of temperature is still greater, when different salts are employed at the same time. Thus, nitrate of ammonia 6 parts, phosphate of soda 9 parts, and diluted nitrous acid 4 parts, all by weight, reduce the temperature of the mixture from 50° to —21°. This is a diminution of 71°, and is the greatest degree of cold that can be procured by a single mixture yet known. Mr Walker succeeded in freezing mercury, by cooling, in a succession of these mixtures, the ingredients by whose liquefaction the congelation was ultimately to be produced, though the temperature of the air at the commencement of the experiment was 45°. Thus, let the mixtures be represented by A, B, C, D: the ingredients for the mixture B were cooled by A; those for C by B; and lastly, those for D by C; so that the ingredients for the last mixtures were at a very reduced temperature, before they were exposed to mutual action with one another.

When ice or snow is dissolved in acids, the solution takes place very rapidly, and is accompanied with a great reduction of temperature. The degree of cold obtained varies with the acids, and even with the state of concentration in which they are employed. Lowitz has ascertained, that, in the undiluted state, muriatic acid produces the greatest cold, nitrous the next, and sulphuric acid the least; the first reducing the temperature from 32° to —29°, the second to —22°, and the third to —11° of Fahrenheit. Sulphuric acid, however, when it is diluted with water, has a more powerful effect than either of the other two. Contrary to what we should have expected, if the acids be cooled so low as to be congealed, they produce, when added in that state to snow, a smaller reduction of temperature than they produce when liquid. The diminution of effect is probably to be ascribed to the solution taking place more slowly.

Solution of snow in acids.

A much greater degree of cold is obtained from the action of the salts with ice or snow, than when these substances are simply dissolved in water. A mixture of snow and common salt, reduces the thermometer to zero on the scale of Fahrenheit. As this was the greatest degree of cold known at the time, when that artist proposed his division of the thermometrical scale, it was conceived to be a very fit point for the commencement of the graduation. It has been ascertained, however, that several other salts have a much greater refrigerating effect, and that some of them produce a cold which is upwards of 70° below that point. The reason why the salts cause a greater reduction of temperature with ice or snow than with water, is evidently the great absorption of caloric which takes place during the liquefaction of the ice or snow, in consequence of the increased capacity in a liquid state.

Having considered the various methods of producing cold by liquefaction, we shall now subjoin a list of the most powerful of the freezing mixtures, the materials to be employed being taken by weight.

Table of Freezing Mixtures.

Table of freezing mixtures.

	Parts.	Reduction of Temperature.
Muriate of Ammonia,	5	from 50° to 10°
Nitre,	5	
Water.	16	
Muriate of Ammonia,	5	50 to 4
Nitre,	5	
Sulphate of Soda.	8	
Water.	16	
Nitrate of Ammonia,	1	50 to 4
Water.	1	
Sulphate of soda,	8	50 to 0
Muriatic acid.	5	
Sulphate of soda,	3	50 to — 3
Sulphuric acid diluted with an equal weight of water.	4	
Sulphate of soda,	3	50 to — 3
Nitrous acid diluted with an equal weight of water.	2	
Nitrate of ammonia,	1	50 to — 7
Carbonate of soda,	1	
Water.	1	
Sulphate of soda,	6	50 to —10
Muriate of ammonia,	4	
Nitre,	2	
Diluted nitrous acid as above.	4	
Phosphate of soda,	9	50 to —12
Diluted nitric acid,	4	
Sulphate of soda,	6	50 to —21
Nitrate of ammonia,	5	
Diluted nitrous acid,	4	
Muriate of soda,	1	32 to — 5
Snow,	2	
Dry carbonate of ammonia,		32 to — 6
Snow,		
Diluted nitrous acid,		32 to —10
Snow,		
Concentrated sulphuric acid,		32 to —10½
Snow,		
Muriate of soda,	2	32 to —12
Muriate of ammonia,	1	
Snow,	5	
Soda crystallized,		32 to —15
Snow,		
Potash, pure, and deprived of its water of crystallization,		32 to —15
Snow,		
Concentrated acetous acid,		32 to —17
Snow,		
Carbonate of potash,		32 to —17
Snow,		
Nitrate of lime,		32 to —17
Snow,		
Muriate of soda,	10	32 to —18
Nitre,	5	
Snow,	24	
Sulphuric acid diluted with half its weight of water,	2	32 to —23
Snow,	3	
Muriate of soda,	5	32 to —25
Nitrate of ammonia,	5	
Snow,	12	
Muriatic acid concentrated,	5	32 to —27
Snow,	8	
Nitrous acid concentrated,	4	32 to —30
Snow,	7	
Muriate of lime,	5	32 to —40
Snow,	4	
Muriate of lime,	3	32 to —50
Snow,	2	
Muriate of lime,	5	32 to —53
Snow,	3	
Muriate of lime,	2	0 to —66
Snow,	1	
Muriate of lime,	3	40 to —73
Snow,	1	
Sulphuric acid diluted with half its weight of water;	10	68 to —91
Snow,	8	

The mixtures in which the proportion of the ingredients are omitted, have been proposed by Lowitz: the materials are probably meant to be employed in equal quantities.

The salts employed should neither be in an efflorescent state, nor contain an excess of water of crystallization; and after being reduced to powder, they should be mixed as quickly as possible with the other materials. In those mixtures in which snow is used, the snow answers the purpose best when it has fallen during frosty weather, and is in a dry pulverulent state. In all cases, the proper proportion of the materials should be carefully observed; an excess of any of them is so much superfluous matter to be cooled down, and must diminish the effect.

Mr Hutton's experiments on the freezing of alcohol.

A cold still more intense than can be procured by any of the freezing mixtures mentioned in the preceding Table has lately been obtained by Mr Hutton, a gentleman in Edinburgh. He has not thought proper to communicate to the public the processes of refrigeration which he has employed; but the results of the cold he obtained, indicate a much greater reduction of temperature than has hitherto been known.

"Directing my attention to this subject," says Mr Hutton, "in the summer of 1810, a method occurred to me, by which I imagined a greater degree of cold might be produced than had hitherto been obtained. Although the power of this method appeared in theory almost indefinite, yet it was easy to foresee, that in practice many circumstances might at first concur to set limits to its application; from the nature of these circumstances, however, it was to be expected that some of them might be considerably modified, and many of them might in time be altogether removed, and thus the practice made in some degree to approximate to the theory.

At the time this method occurred to me, the pressure of my professional avocations did not allow me to prosecute it; but, as I anticipated some leisure in the following autumn, I immediately began to provide at any leisure moments I had, such apparatus as I considered absolutely necessary, or was most likely to be useful. The little dependance, however, which is to be placed on general reasoning on such subjects, and the apprehension that the method might have been previously tried, and found insufficient by others, prevented me from providing any very extensive apparatus.

My first experiment was tried in the following autumn. The thermometer was filled and sealed by myself. The tube was previously tried by the common method, and found, as nearly as such tubes are commonly to be met with, of equal calibre throughout. The spirit with which it was filled, was prepared by Richter's process, and afterwards re-distilled by itself.—Its specific gravity at 62° was 798.—The points 60° and 100° were determined by a mercurial thermometer, which had been made with the usual precautions; the interval was divided into four spaces, each of which, of course, corresponded to 10°; the part of the stem below 60° measured nearly 18 of these spaces. A mark was made at every space, till, on arriving at the end of the 17th, the graduation could not be carried farther. This point, of course, corresponded to $+60° - 170° = -110°$ of Fahrenheit's scale.

This thermometer was exposed to the cold produced by the method alluded to, and after some time was examined, when the alcohol was found to have passed all the marks, and was obviously sunk within the ball of the thermometer. A slight degree of discoloration was observable. The thermometer was replaced, and examined about five minutes afterwards, when the ball of the thermometer was found broken, and crystals adhered to the fragments.

I next took a glass tube, about 3-10ths of an inch in diameter, and sealed at one end; into this I poured alcohol till it stood in the tube 4 10ths of an inch deep, and then exposed it to the cold, produced as before; after some time, it was so completely solid, that on inverting the tube it did not drop, and only a very minute stream was perceived to glide slowly down the inside of the tube; when this stream had reached nearly the middle of the tube, the whole suddenly fell out, and, pitching in a glass, was broken into several pieces, which quickly melted.

This experiment was several times repeated, but by allowing the alcohol to remain a little longer exposed to the cold, it became so completely solid, that, on inverting the tube, not the least portion of fluid could be perceived to separate from the mass.

Mr Hutton's experiments on the freezing of alcohol.

In order to be as certain as possible of the strength of the alcohol I employed, I again took its specific gravity, and the result corresponded with what I before obtained.

These experiments, therefore, left me no room to doubt that I had frozen alcohol, which, at the temperature of 62°, is of the specific gravity 798.

Being appointed (by the Edinburgh Institute) to deliver the course of lectures on chemistry for the session 1810-11, I had no leisure at that time to pursue these experiments. They were resumed, however, in the autumn of 1811. The second experiment was repeated and varied, and solid masses of alcohol of some magnitude obtained. Some of these I soldered together, using as a hot bolt a rod of frozen mercury, and sometimes a straw cooled down to a very low temperature.

It now appeared to me to be an object of some importance, to ascertain the form of the crystals which this substance assumes. This I found attended with some difficulties which I did not anticipate, and attempts to overcome them, have led to the discovery of some facts which I did not at all expect.

The common masses exhibited crystals of different forms; two kinds appeared to predominate, and each was tolerably distinct in its kind, but it was not very easy to perceive by what increments or decrements the one could be supposed to pass into the other; a rather casual circumstance, however, explained the source of this variety. Attempting to freeze alcohol by a modification of the general process, which I conjectured would yield more regular crystals than the common method, I observed, that before crystallizing, the alchohol separated into three very distinct strata, the uppermost was of a pale yellowish green, while the second was of a very pale yellow colour. Both these strata were very thin, the last mentioned was rather the thickest; the lowermost stratum was nearly transparent and colourless, and very greatly exceeded the other two in quantity. After allowing a part of the lower stratum, which I conceived to be the pure alcohol, to freeze, I attempted to pour out the remainder, but was prevented by the upper strata, which proved to be solidified. The lowermost of these two strata bore some marks of crystallization, the upper had none, and proved so firm as to resist a straw, with which I attempted to perforate it, to open a passage for the sublatent liquid. On removing part of these superior strata, and decanting the remaining fluid, the crystals of the lower stratum appeared very distinctly to be rectangular prisms of equal planes, a few of them on one side of the glass surmounted by quadrangular pyramids, but most of them by dihedral summits. This experiment I repeated several times, and the results coincided.

In order to ascertain whether these phenomena arose from a decomposition of the alcohol, or from the separation of foreign substances previously held by it in solution, the products of several of these experiments were mingled together in a stoppered matrass; the whole was then raised to the temperature of about 120°, by a water bath of that temperature. The substances forming the different strata united together, and formed a colourless liquor, which had the specific gravity and all the other properties of the alcohol from which it was obtained. This experiment was repeated several times, and the results were uniform, affording sufficient evidence that the alcohol had not been decomposed by this process, but that the superior strata consisted of foreign substances

Mr Hutton's experiments on the freezing of alcohol.

which it had held in solution. The variety in the form of the crystals obtained by former experiments, was therefore most likely occasioned by the presence of these foreign substances, a phenomenon not uncommon in chemistry.

The result of these experiments led me now to perceive, that the assumption that alcohol, prepared by Richter's process, is perfectly pure, or at most contains only a very minute portion of water, is entirely gratuitous. The diluted alcohol of commerce, from which the more concentrated is obtained, is well known to contain different volatile impurities; and since Richter's process makes no provision for the separation of these, we ought rather to expect still to meet with some portion of them in alcohol prepared in this manner.

I next proceeded to examine the properties of the different substances into which I had separated Richter's alcohol, but the time I had now left for this purpose was too short for making much progress in this inquiry; a few only of their habitudes with water, and with one another, were all that I had time to examine; even these I could examine only imperfectly.

The lowermost stratum, or nearly colourless fluid, which I have called alcohol, had no flavour, and produced on the organ of smell only a sharp pungent sensation. It has the remarkable property of smoking when exposed to the air, and, when diluted with water, it differs considerably in taste from common diluted spirit of wine.

I have made no experiments to ascertain the specific gravity of this alcohol. It may at first sight be concluded, that, by being deprived of its impurities, which are evidently specifically lighter than it, this alcohol would have its specific gravity increased: such a conclusion, however, would be obviously rash; for, since these impurities were, without doubt, previously in combination with the alcohol, and when mixed with it again enter into that state, and since, by this kind of combination, the mean specific gravity is generally altered, most frequently increased—supposing that this combination follows the more general law, the increase may be either greater or less than the diminution occasioned by the lighter impurities; and therefore, for any thing we at present know, the specific gravity of this alcohol may be either greater or less than that of the compound from which it is obtained.

The pale yellow substance, or second stratum, has a pungent taste, leaving an impression of sweetness. It has a very strong but agreeable smell. When mixed with the alcohol, and diluted with water, it has very much the flavour of the better kinds of highland whisky. It readily dissolves in water, and communicates to that fluid its peculiar flavour.

The pale yellowish green substance which composes the uppermost stratum, has a strong and very offensive smell, and a very sharp nauseous taste. It dissolves in alcohol, to which it communicates its peculiar flavour; its disagreeable smell is considerably heightened by this combination. It dissolves in water, though less readily than the substance last treated of. The compound, when much diluted and heated, has very much the flavour of the *low wine* of our lowland distillers, at the time when it issues from the still.

The two last mentioned substances, or those of which the two upper strata are composed, when mixed together and greatly diluted with water, have very nearly the flavour of alcohol. They have rather more volatility than water; for when half of a solution of them has been distilled over, the distilled part has a much stronger smell than that which remains in the retort. The kind of smell, however, of both portions is the same, which shows that these impurities cannot be separated by distillation.

It may be proper to mention, that from the circumstance of my sense of smell having been for some time extremely obtuse, I have been under the necessity of trusting to others for the facts regarding the flavour of these new substances and mixtures. From the uniformity of the reports, however, which I have received from different persons, I have no doubt that these facts are correct.

Besides that from which I filled the thermometer in the first experiment, I have operated on alcohol of the specific gravities 802, 797, and 784. the specific gravity of the last was taken when its temperature was 66°, and it is probably the most concentrated that has ever been obtained. But with alcohol of all these different strengths, the general results were similar. In alcohol obtained from different sources, the proportions of the impurities were different, both with regard to the pure alcohol, and to one another, but I have met with none that did not contain both.

From these experiments I think it is ascertained,

1st, That the strongest alcohol which we are able to obtain, may be frozen by the method alluded to.

2d, That this alcohol contains at least two foreign substances, which are highly volatile, and, so far as is known, can only be separated by freezing.

3d, That it is to these substances that alcohol owes its peculiar flavour, and that, according as the one or other predominates, the flavour of the alcohol is agreeable or otherwise.

Last autumn (of 1812) I resumed this subject, and my attention was chiefly directed to the habitudes of these impurities with the chemical re-agents. This I found attended with considerable difficulties, none of the least of which was to procure a sufficient quantity of these impurities in a separate state. The series of experiments I proposed to myself on this subject have not yet been completed, but I may remark, that the result of some of those I have made promises to afford practical hints of considerable importance to those brewers, whose products are intended to afford spirituous liquors.

From this notice it will be observed, that I have scarcely yet entered on the wide field of inquiry, for the cultivation of which, the method alluded to appears to offer so powerful an instrument. Alcohol only has been subjected to experiment; it was the only liquid which had resisted all attempts to reduce it to the solid state by the abstraction of caloric. If these experiments be correct, we may now pronounce it a general law to which there is no exception, that all liquids with which we are acquainted, may be reduced to the solid state by a suitable abstraction of caloric. Whether all gases may be susceptible of reduction to the solid state, by the abstraction of caloric, remains to be ascertained; although, as I have mentioned, analogy renders it in the highest degree probable."

Radiation of cold.

Before finishing the consideration of artificial cold, we must offer a few remarks on a fact, the explanation of which seems to have given a great deal of difficulty to chemists,—we mean the apparent radiation of cold. The discussion of this subject is important, in a scientific point of view, from its connection with the question concerning the existence of a frigorific principle, as an antagonist to caloric. We do not pretend that we shall set this question at rest; but we are satisfied we shall be able to prove, that the existence of cold, as a separate and independent principle or condition of matter, receives no additional support from the fact of its apparent radiation.

The effect of surface in modifying the heating and cooling of bodies by radiation, has been long known; though we are indebted to Mr Leslie for the first scientific investigation of the subject. Some experiments on radiation had, indeed, been made by Lambert and Scheele, but they were extremely obvious, and have little pretensions to precision.

If a plate of polished metal be exposed to the heat of a fire, almost all the rays of caloric are reflected from its surface, and it requires but little increase of temperature. But if a pane of glass be placed in similar circumstances, the greater part of the rays are absorbed, and the pane soon becomes very warm. The same effect is produced, if the surface of the metallic plate be covered with a coating of lamp-black. From those experiments, and a variety of others which will be detailed under HEAT, it appears that the absorbing power of bodies for caloric is considerably affected by the nature of their surfaces. It is somewhat curious, that when their temperature is superior to that of the surrounding medium, or adjacent bodies, their tendency to radiate, or throw off caloric, corresponds with their disposition in the former case to absorb it; so that the absorbing and radiating power, or in common language, the tendency to heating and cooling in opposite circumstances, are equally affected by surface, and in a degree that has some relation to the distance and difference of temperature of the radiating and absorbing bodies; the radiation and absorption being carried on between them, until an equilibrium of temperature is established. It is difficult to determine, whether a mutual interchange of temperature takes place between the warmer and the colder bodies, each radiating in a degree corresponding to its quantity of caloric, or whether the radiation proceeds from the warmer body alone, and the colder body is merely a recipient of its emanations; only, if we say that one body is hot, and the other cold, we must affirm, in conformity with the ordinary acceptation of the terms, that, in the latter supposition, there is a radiation of cold as well as of heat. Thus, let the temperature of the hotter body be 60° of Fahrenheit, and that of the colder 30°: if it be supposed, that a mutual communication of temperature by radiation takes place between them, we would admit without hesitation that the colder body radiates cold; or, if it be supposed that the temperature of the one is 30°, and that of the other 20°, and that the radiation proceeds solely from the body at the more elevated temperature, we might still say that the emanations were cold. But if the temperature of the hotter body were 120°, and that of the colder 60°, we would scarcely be disposed to admit that the latter radiated cold, even on the supposition of a reciprocal exchange of temperature. In those instances, however, it is obvious that we assume our own feelings as the standard of reference; and though, in the discussion of the radiation of cold, this circumstance has been sometimes brought into view, we suspect it has been too little regarded; and that it has contributed, either directly or indirectly, to produce all the obscurity in which the radiation of cold is at present involved. If we reject entirely the decision of our feelings, as vague and fallacious, and have recourse to the less objectionable means of describing the degrees of temperature by the expansion and contraction of bodies, we shall be compelled to acknowledge, that as we are still ignorant of the true zero, or the point of total privation of temperature, we cannot, in any case, pronounce with certainty whether the radiation be of a calorific or frigorific nature. Nay as we judge ultimately of the reduction of temperature in every case by the contraction of bodies, it is evident that so long as this contraction takes place, we must infer that caloric is abstracting from them; and as this may continue to go on until the bodies are reduced to mere physical points, the true zero and the annihilation of matter must be coincident; in other words, matter cannot exist without having a certain temperature, or a certain degree of caloric is essentially connected with it from its very nature. If this view of the subject be just, the opinion of the radiation of cold must be rejected, as founded entirely on the vague use of the terms which we apply to the radiation of temperature in different circumstances, and which, by a slight change of these, may become a radiation of caloric.

The total privation of temperature seems to imply an impossibility or at least the annihilation of matter.

Several experiments, however, have been adduced, which seem to afford the same evidence for the existence of a frigorific principle, that we have of caloric. These experiments are all connected with radiation or absorption: after describing them, we shall state the hypotheses which have been proposed to explain them, in conformity with the opinion that cold is merely the abstraction of caloric.

We have already mentioned, that when a plate of polished metal is exposed to a heated body, almost all the rays of caloric are reflected. If the rays strike the surface of the plate perpendicularly, they are reflected directly backwards; but if they strike it obliquely, they are also reflected obliquely; and the angle of reflection, as in the case of light, is equal to the angle of incidence. Such a figure, therefore, might be given to the metallic surface, that when the heated body to which it is exposed is placed in a certain position, all the rays incident upon it might be reflected in a direction parallel to each other. This will be the case if the metallic reflector have the surface of a parabolic conoid, and the hot body be placed in the focus of the generating parabola. Accordingly, if another mirror of the same form be placed directly opposite, the foci being turned towards each other, and the axes coincident, the emanations from the hot body in the one focus will meet, after two reflections, in the other, and produce there an elevation of temperature corresponding to that of the hot body. If the surface of the reflectors be coated with lamp black, the effect is scarcely perceptible, because almost all the rays of caloric are then absorbed. In short, the greatest effect is produced, when the surface of the hot body is most favourable to radiation, the temperature being supposed the same; and when the reflectors are most highly polished, and formed of some metal which has the least disposition to absorb caloric.

Experiment of Pictet.

It was ascertained by Pictet, with an apparatus similar to the one we have described, that when a matrass filled with snow was placed in the one focus, and a delicate air thermometer in the other, the reflectors being at the distance of 10½ feet, the thermometer immediately indicated a reduction of temperature of several degrees, and rose again when the matrass was withdrawn. On replacing the matrass, and pouring nitrous acid upon the snow, the temperature of the thermometer sunk 5° or 6° lower than before. In this experiment, cold seems to have been radiated by the snow, and after being reflected from the surface of each mirror, to have been absorbed by the thermometer; and hence the reduction of temperature which it sustained.

Experiments of Mr Leslie.

In order to ascertain the nature of this radiant cold, Mr Leslie, who has particularly investigated the subject by experiment, took a tin cubical vessel, having one side painted with lamp black, another coated with writing paper, a third covered with a pane of glass, and the fourth bright and polished: he filled the vessel thus prepared with ice, and having opposed it to the thermometer in the focus of one of the reflectors, he found the reduction of temperature sustained by the thermometer to be least from the metallic surface, greater from the pane of glass, and greatest of all from the side coated with lamp-black. From a variety of other experiments, he ascertained, that the powers of different substances in radiating, reflecting, and absorbing cold, are precisely the same as their powers of radiating, reflecting, and absorbing heat. Hence, it has been concluded, that we have the same proofs for the existence of cold as a distinct and independent principle, that we have for the existence of heat.

Explanation of the apparent radiation of cold by Prevost.

The explanation of these facts, in conformity with the doctrine that cold is merely a negation of heat, has given greater difficulty to chemists than we conceive belongs naturally to the subject. According to the hypothesis of Prevost, caloric is radiated from all bodies at all temperatures, the quantity radiated being proportional to the difference of temperatures. When the body placed in the focus of one of the reflectors has a more elevated temperature than the thermometer in the focus of the opposite reflector, the temperature of the thermometer is increased, because it receives more caloric by absorption, than it communicates by radiation. When both the body and the thermometer are at the same temperature, no change takes place, because each communicates the same quantity which it receives; but if the temperature of the body be lower than that of the thermometer, though it still radiates caloric, it radiates a smaller quantity than the thermometer, and therefore the temperature of the latter is reduced.

Objections to it.

This explanation, depending upon the assumed principle, that bodies, at all temperatures, radiate caloric in a degree proportional to the quantity of that power which they contain, is totally inconsistent with the most obvious facts attending the cooling of bodies. For, if it were true that a mutual participation of temperature takes place between the hotter and the colder body, until they arrive at the same temperature, and that this reciprocal action even goes on after an equilibrium is established between them, it is evident that a hot body ought to cool more slowly when it is placed near a large body of inferior temperature, than near a small one; because, in the former case, (as we must suppose, that if a body radiates at all, the radiation will at least be proportional to its surface), it must receive more calorific emanations than in the latter; and this, of course, ought to retard its cooling. But the fact is precisely the reverse. It is also very properly objected to this explanation by Mr Murray, that "of different surfaces, which at a given temperature radiate different quantities of caloric, that which radiates least must be least powerful in returning caloric to the thermometer, and must therefore have least effect in counteracting the reduction of its temperature; in other words, must produce the greatest cold. From Mr Leslie's experiments, it is fully established, as has been already stated, that a blackened surface is that which, at a given temperature, radiates the largest quantity of caloric, and a metallic surface that which radiates least. Were Prevost's explanation just, therefore, the blackened surface is the one which, in the experiment on radiant cold, ought to produce the least cooling effect on the thermometer, and the metallic surface the greatest." Rejecting, therefore, this explanation of Prevost, we shall proceed to consider that of Pictet.

Explanation of Pictet.

According to this philosopher, the particles of caloric have a repulsion to each other, which increases as the distance between them diminishes. They therefore tend to recede from each other with a force proportioned to the degree of their accumulation in the same body, and separate, until they are counteracted by caloric in other bodies, of the same density or elasticity with themselves. So that, if this hypothesis be well-founded, the term *equilibrium* of temperature may be applied with strict propriety to the equal distribution of it, as being, in reality, the balancing of equal and opposite forces. But if a body, at a lower temperature, be introduced among a system of bodies in this state of equilibrium, the particles of caloric of the colder body are forced to approach nearer to each other by the more powerful elasticity of the caloric of the hotter bodies; a fresh supply enters to occupy the space which they had left; and the balance of tension being again restored, an equilibrium of temperature is quickly established. When a cold body is placed in the focus of one of the reflectors, the equilibrium of temperature of the surrounding bodies is subverted, and caloric immediately rushes towards it from every side. The adjacent surface of the reflector is thus deprived of a portion of its caloric, and the deficiency is partially supplied by the opposite reflector. This reflector, in its turn, begins to act upon the thermometer, which, by this series of radiations and absorptions successively repeated, is drained of its caloric, and reduced in temperature. This explanation, though free from the objections which we have stated against the hypothesis of Prevost, is irreconcileable with the fact, that the greatest reduction of temperature is produced in the thermometer, when the reflectors are in the most unfavourable state for radiation and absorption, the effect in similar circumstances being greatest when the reflectors are well polished and resplendent. But if the theory were just, it is obvious that the very reverse would be the case; and that the greatest apparent radiation of cold would be exhibited when the surface of the reflectors were covered with a coating of lamp-black; because, in that state, they possess the greatest radiating and absorbing power, whereas the effect is then barely perceptible. This theory is therefore equally inadmissible with the former.

Objections to it.

The theory of Prevost not more inapplicable to the experiments with the reflectors, than to ordinary radiation.

With respect to the theory of Prevost, we may remark, that the same objection may be urged in applying it to the most simple case of cooling,—that of a thermometer being reduced in temperature when it is placed near a cold body, as in the experiments with the reflectors. The truth is, that as the only effect of the reflectors is to change *mechanically* the direction of the emanation, and thus establish a communication between the remote sides of the cold body and the thermometer, there is no greater difficulty in accounting for the reduction of the temperature of the thermometer in these circumstances, than when a thermometer is cooled directly in consequence of its proximity to a cold body. So that the objection of Mr Murray against this theory, that the reduction of the temperature of the thermometer was greatest, when the surface of the cold body was most favourable to radiation, may be applied with equal force to the simplest case of radiation we can suppose. The imperfection of Prevost's theory does not consist, therefore, merely in its insufficiency to explain the experiments with the reflectors, but in its being equally inapplicable to explain the phenomena attending the changes of temperature by direct and immediate radiation.

Modification of Pictet's theory.

With regard to the explanation advanced by Pictet, the objections to which it is liable in its present form, might, in some measure, have been avoided, by taking a different view of the action of the mirrors. The general theory which he has proposed for explaining the processes of the heating and cooling of bodies, does not necessarily imply that the mirrors shall act solely by absorption and radiation; and, indeed, the author of the theory seems to have adopted that view of the subject, from the difficulty which he had found of accounting for the emanations proceeding from the thermometer, when its temperature was the same as that of the surrounding medium. According to Pictet's hypothesis, if two equal and similar bodies, at the same reduced temperature, were placed, one in the focus of each reflector, they would have no effect upon each other, as the elasticity of the calorific fluid in both being exactly balanced, the equilibrium of temperature would be maintained between them. But if a hot body, as a thermometer, were substituted for one of the cold bodies, the equilibrium would immediately be subverted; and the caloric of the thermometer diffusing itself by its superior elasticity, would rush towards the adjacent mirror, undergo reflection at its surface, and proceed in parallel lines to the opposite mirror, where it would suffer a second reflection, and at last be absorbed by the cold body. Of course, the temperature of the thermometer would be reduced, and thus indicate the appearance of the radiation of cold from the cold body.

Without adopting the explanation either of Prevost or Pictet, or advancing any hypothesis of our own on the subject, we shall deem it sufficient to shew that the results of the experiments with the reflectors afford no argument for the support of any theory, which might not be derived from direct radiation and absorption.

Attempt to shew that the experiments with the reflectors, furnish no new argument for the radiation of cold.

Plate CXCIX. Fig. 5.

That we may begin with the simplest case, let it be supposed that the body A, Plate CXCIX, Fig. 5, is surrounded on every side with bodies at an inferior temperature: it will immediately begin to throw off rays of caloric in all directions, and if the surrounding bodies be regularly and uniformly disposed, and have the same absorbing powers for caloric, it will cool equally on every side. If another body B, in every respect similar to A, at a temperature considerably lower than that of the other bodies, be now placed at no great distance from A, the body A will cool more rapidly than before, particularly on the side adjacent to B; and still more rapidly if the surfaces *a d*, and *f h*, possess great radiating or absorbing powers. Since the cooling of A is promoted by the nature of the surface *f h* of B, and since those surfaces which radiate caloric most powerfully, also absorb it in the same degree in opposite circumstances, it is obvious, that any hypothesis which assumes, that emanations proceed mutually from one body to the other, during the process of cooling, must have the same difficulty in explaining why, in the present case, A is more rapidly reduced in temperature, when the radiation from B ought to be most abundant, as it would have in similar circumstances with the reflectors. Consequently, the objections which we urged against Prevost's theory, deduced from the experiment with the reflectors, that the greatest depression of the thermometer is exhibited when the surface of the cold body, placed in the focus of one of the reflectors, is most favourable to radiation, apply with equal force in cases of cooling by direct radiation and absorption.

Let us now suppose that the radiations from the side *b c*, instead of being allowed to proceed from it in their ordinary course, are intercepted by some reflecting surface, and thrown back in the same direction with the perpendicular emanations from the opposite side *a d*; as this reflection can have no effect on the physical qualities of the emanations, but merely to change their direction, the only consequence of the arrangement we have supposed will be to retard slightly the cooling of A, by the partial re-absorption of those rays which are thrown back upon *b c*. If we further suppose, that the reflected emanations now moving parallel to one another, are again intercepted by a reflecting surface placed behind B, and thrown by means of its figure upon the surface *e g*, the same effect must now be produced on this surface as if there had been a direct radiation towards it from *b c*. Indeed, it might be inferred, *à priori*, that as the only function of the reflecting surfaces is to change the direction of the incident rays, we have no reason to expect, when they are employed, any effect different from that which is obtained by immediate and direct radiation.

We accordingly find, that the greatest effect is produced in diminishing the temperature of A, when the surfaces *b c* and *e g* are best fitted to radiate and absorb the calorific rays, just as we found the same thing to hold by direct radiation, when the surfaces *a d* and *f h* were in like circumstances. It is evident, therefore, that the rapid cooling of a hot body, when it is placed in the focus of a reflector by means of a cold body placed in the focus of an opposite reflector, admits of being explained upon any hypothesis which affords a satisfactory explanation of the simplest case of cooling, that by direct radiation; and that the experiments with the reflectors furnish no argument in support of the doctrine of a frigorific principle of which we were not previously in possession.

Natural cold.

The degrees of natural cold which occur in the more inhospitable regions of the globe, are far surpassed by the reductions of temperature obtained by artificial means. The greatest cold that has hitherto been observed in the open air, does not exceed —50; and probably the extreme range of the inferior temperatures which occur in nature, is but little below that point.

The temperature of a particular place on the surface of the earth is determined by a variety of circumstances, some of which are regular in their operation, others accidental. Among the former of these, may be stated, the direct influence of the solar rays, and the latitude; among the latter, the winds, evaporation, and perhaps the evolution or absorption of heat by operations going on in the central regions. Even the causes of temperature which we have denominated regular, are not absolutely so: the heat produced by the rays of the sun may be affected by spots upon his surface; and the temperature resulting from geographical position may be modified by local peculiarities. Thus the sea limits the range of temperature, by moderating alike the extremes of heat and cold; while large tracts of land are equally favourable to both. The winds have a very powerful influence on the temperature of a place. When the surface of the earth is much heated by the influence of the solar rays, the air immediately above it is rarified, and becoming specifically lighter, ascends into the higher regions of the atmosphere. Its place is quickly occupied by a fresh portion of air rushing in from every side, which, in its turn, being heated and rarified, also ascends. The warm air which has thus ascended, is gradually wafted to colder regions, where it gives out its heat, and moderates the rigour of the climate to which it has been transported.

Remarkable change on the climate of Europe.

Evaporation is one of the principal sources of natural cold, the conversion of water into vapour being necessarily accompanied with the absorption of much caloric; hence, the agricultural improvement of a country, or whatever tends to facilitate the escape of the water from its surface by any means but evaporation, has a remarkable influence on its temperature. The gradual amelioration of the climate of America, is undoubtedly to be ascribed to this cause, as well as that of Europe. Hume, in his *Essay on the Populousness of Ancient Nations*, has proved, by the most ample authorities, that a very great change has taken place on the general temperature of Europe since no very distant period: "It is an observation of L'Abbe de Bos," says he, "that Italy is warmer at present than it was in ancient times. The annals of Rome tell us, that in the year 480 *ab* U. C. the winter was so severe that it destroyed the trees; the Tyber froze at Rome, and the ground was covered with snow for forty days. When Juvenal describes a superstitious woman, he represents her as breaking the ice of the Tyber, that she might perform her ablutions:

> *Hybernum fracta glacie descendet in amnem,*
> *Ter matutino Tyberi mergetur.*

He speaks of that river's freezing as a common event. Many passages of Horace suppose the streets of Rome full of snow and ice. We should have more certainty with regard to this point, had the ancients known the use of thermometers; but their writers, without intending, give us information sufficient to convince us, that the winters are now much more temperate at Rome than formerly. At present, the Tyber no more freezes at Rome than the Nile at Cairo. The Romans esteem the winter very rigorous, if the snow lie two days, and if one see, for eight-and-forty hours, a few icicles hang from a fountain that has a north exposure.

"The observation of this ingenious critic," continues Hume, "may be extended to other European climates. Who could discover the mild climate of France in Diodorus Siculus's (lib. iv.) description of that of Gaul? As it is a northern climate,' says he, 'it is infested with cold to an extreme degree. In cloudy weather, instead of rain there fall great snows; and in clear weather, it there freezes so excessive hard, that the rivers acquire bridges of their own substance; over which, not only single travellers may pass, but large armies, accompanied with all their baggage and loaded waggons. And there being many rivers in Gaul, the Rhone, the Rhine, &c. almost all of them are frozen over; and it is usual, in order to prevent falling, to cover the ice with chaff and straw at the places where the road passes. *Colder than a Gallic winter*, is used by Petronius as a proverbial expression. Aristotle says, (*De Generat. Anim.* lib. ii.) that Gaul is so cold a climate that an ass could not live in it.

"North of the Cevennes," says Strabo, (lib. iv.) "Gaul produces not figs and olives; and the vines which have been planted bear not grapes that will ripen.

"Ovid (*Trist.* lib. iii. eleg. 9.) positively maintains, with all the serious affirmation of prose, that the Euxine sea was frozen over every winter in his time; and he appeals to Roman governors, whom he names, for the truth of his assertion. This seldom or never happens at present in the latitude of Tomi, whither Ovid was banished. All the complaints of the same poet seem to mark a rigour of the seasons, which is scarcely experienced at present in Petersburgh or Stockholm.

"Tournefort, a *Provençal*, who had travelled into the same country, observes, that there is not a finer climate in the world; and he asserts, that nothing but Ovid's melancholy could have given him such dismal ideas of it. But the facts mentioned by that poet, are too circumstantial to bear any such interpretation.

"Italy, says Varro, (lib. i. cap. 2.) is the most temperate climate in Europe. The inland parts, (Gaul, Germany, and Pannonia, no doubt,) have almost perpetual winter.

"The northern parts of Spain, according to Strabo, (lib. iii.) are but ill inhabited, because of the great cold."

These extracts afford the most satisfactory evidence, that the climate of Europe is much milder than it was in ancient times. The difference is undoubtedly owing to the partial clearing of the woods, and the land being better cultivated now than formerly; so that the superfluous water, which at that time was carried off in a great measure by evaporation, is conveyed away by drains and canals.

The winter cold of the northern parts of Europe is still more than sufficient to freeze mercury. The congelation of this metal by natural cold, was first observed at Krasnojark, in lat. 56° 30′, long. 93° east. Mercury is said to have been sometimes frozen at Quebec, in lat. 47°.

The following narrative, written by Captain Middleton, F. R. S. contains so minute a description of the effects of natural cold during winter at Churchill's river, in Hudson's Bay, and is so applicable to the general effects of cold in other places, that we shall make no apology for giving it in his own words.

Account of the winter cold at Hudson's Bay.

"The lakes and standing waters, which are not above 10 or 12 feet deep, are frozen to the ground in winter, and the fishes therein all perish.

Yet in rivers near the sea, and lakes of a greater depth than 10 or 12 feet, fishes are caught all the winter, by cutting holes through the ice down to the water, and therein putting lines and hooks. But if they are to be taken with nets, they cut several holes in a straight line the length of the net, and pass the net, with a stick fastened to the head-line, from hole to hole, till it reaches the utmost extent; and what fishes come to these holes for air, are thereby entangled in the net; and these fishes, as soon as brought into the open air, are instantaneously frozen as stiff as stock-fish. The seamen likewise freshen their salt provisions, by cutting a large hole through the ice in the stream or tide of the river, which they do at the beginning of winter, and keep it open all that season; in this hole they put their salt meat, and the minute it is immersed under water, it becomes pliable and soft, though before its immersion it was hard frozen.

Meat preserved by being frozen.

Beef, pork, mutton, and venison, that are killed at the beginning of winter, are preserved by the frost for six or seven months, entirely free from putrefaction, and prove tolerably good eating. Likewise geese, partridges, and other fowl, that are killed at the same time, and kept with their feathers on and guts in, require no other preservative but the frost to make them good wholesome eating, as long as the winter continues. All kinds of fish are preserved in the like manner.

In large lakes and rivers, the ice is sometimes broken by imprisoned vapours; and the rocks, trees, joists, and rafters of our buildings, are burst with a noise not less terrible than the firing of a great many guns together. The rocks which are split by the frost, are heaved up in great heaps, leaving large cavities behind; which I take to be caused by imprisoned watery vapours, that require more room when frozen, than they occupy in their fluid state. Neither do I think it unaccountable, that the frost should be able to tear up rocks and trees, and split the beams of our houses, when I consider the great force and elasticity thereof. If beer or water is left in mugs, cans, or bottles, nay in copper pots, though they were put by our bedsides, in a severe night they are surely split to pieces before morning, not being able to withstand the expansive force of the inclosed ice.

Effect of the frost on the glasses of telescopes.

The air is filled with innumerable particles of ice, very sharp and angular, and plainly perceptible to the naked eye. I have several times, this winter, tried to make observations of some celestial bodies, particularly the immersions of the satellites of Jupiter, with reflecting and refracting telescopes; but the metals and glasses, by that time I could fix them to the object, were covered a quarter of an inch thick with ice, and thereby the object rendered indistinct, so that it is not without great difficulties that observations can be taken.

Bottles of strong beer, brandy, strong brine, spirits of wine, set out in the open air for three or four hours, freeze to solid ice. I have tried to get the sun's refraction here to every degree above the horizon, with Elton's quadrant, but to no purpose, for the spirits froze almost as soon as brought into open air.

The frost is never out of the ground, how deep we cannot be certain. We have dug down 10 or 12 feet, and found the earth hard frozen in the two summer months; and what moisture we find five or six feet down, is white like ice.

The waters or rivers near the sea where the the current of the tide flows strong, do not freeze above 9 or 10 feet deep.

All the waters we use for cooking, brewing, &c. is melted snow and ice. No spring is yet found free from freezing, though dug never so deep down.

All waters inland are frozen fast by the beginning of October, and continue so till the beginning of May.

The walls of the house we live in are of stone, two feet thick; the windows very small, with thick wooden shutters, which are close shut 18 hours every day in the winter. There are cellars under the house, wherein we put our wines, brandy, strong beer, butter, cheese, &c. Four large fires are made in great stoves, built on purpose, every day. As soon as the wood is burnt down to a coal, the tops of the chimneys are close stopped with an iron cover; this keeps the heat within the house, (though at the same time the smoke makes our heads ache, and is very offensive and unwholesome); notwithstanding which, in four or five hours after the fire is out, the inside of the walls of our houses and bed-places will be two or three inches thick with ice, which is every morning cut away with a hatchet. Three or four times a day we make iron shot of 24 pounds weight red-hot, and hang them up in the windows of our apartments. I have a good fire in my room the major part of 24 hours, yet all this will not preserve my beer, wine, ink, &c. from freezing.

For our winter dress, we make use of three pair of socks of coarse blanketing or duffield for the feet, with a pair of deer skin shoes over them; two pair of thick English stockings, and a pair of cloth stockings upon them; breeches lined with flannel; two or three English jackets, and a fur or leather gown over them; a large beaver cap, double, to come over the face and shoulders, and a cloth of blanketing under the chin; with yarn gloves, and a large pair of beaver mittings hanging down from the shoulders before, to put our hands in, which reach up as high as our elbows; yet notwithstanding this warm cloathing, almost every day, some of the men that stir abroad, if any wind blows from the northward, are dreadfully frozen; some have their arms, hands, and face blistered and frozen in a terrible manner, the skin coming off soon after they enter a warm house, and some have lost their toes. Now their lying-in for the cure of these frozen parts, brings on the scurvy in a lamentable manner. Many have died of it, and few are free from that distemper. I have procured them all the helps I could, from the diet this country affords in winter, such as fresh fish, partridges, broths, &c. and the doctors have used their utmost skill in vain; for I find nothing will prevent that distemper from being mortal, but exercise and stirring abroad.

Coronæ and *parhelia*, commonly called Halo's, and mock-suns, appear frequently about the sun and moon here. They are seen once or twice a week about the sun, and once or twice a month about the moon, for four or five months in winter, several coronæ of different diameters appearing at the same time.

I have seen five or six parallel coronæ concentric with the sun several times in winter, being for the most part very bright, and always attended with parhelia or mock-suns. The parhelia are always accompanied with coronæ, if the weather is clear; and continue for several days together, from the sun rising to his setting. These rings are of various colours, and about forty or fifty degrees in diameter.

The frequent appearance of these phænomena in this frozen clime seems to confirm Descartes's hypothesis, who supposes them to proceed from ice suspended in the air.

The aurora borealis is much oftener seen here than in England; seldom a night passes in winter free from their appearance. They shine with a surprising brightness, darkening all the stars and planets, and covering the whole hemisphere: their tremulous motion from all parts, the beauty, and lustre, are much the same as in the northern parts of Scotland and Denmark.

The dreadful long winters here may almost be compared to the polar parts, where the absence of the sun continues for six months; the air being perpetually chilled and frozen by the northerly winds in winter, and the cold fogs and mists obstructing the sun's beams in the short summer we have here; for notwithstanding the snow and ice is then dissolved in the low lands and plains, yet the mountains are perpetually covered with snow, and incredible large bodies of ice continue in the adjacent seas.

If the air blows from the southern parts, the air is tolerably warm, but very cold when it comes from the northward; and it seldom blows otherwise than between the north-east and north-west, except in the two summer months, when we have, for the major part, light gales between the east and the north, and calms.

The northerly winds being so extremely cold, is owing to the neighbourhood of high mountains, whose tops are perpetually covered with snow, which exceedingly chills the air passing over them. The fogs and mists that are brought here from the polar parts in winter, appear to the naked eye in icicles innumerable, as small as fine hairs or threads, and pointed as sharp as needles. These icicles lodge in our clothes; and, if our faces or hands be uncovered, they presently raise blisters as white as a linen cloth, and as hard as horn. Yet if we immediately turn our backs to the weather, and can bear our hand out of our mitten, and with it rub the blistered part for a small time, we sometimes bring the skin to its former state: if not, we make our way to a fire, and get warm water, wherewith we bathe it, and thereby dissipate the humours raised by the frozen air; otherwise the skin would be off in a short time, with much hot, serous, watery matter coming from under along with the skin; and this happens to some almost every time they go abroad for five or six months in the winter, so extremely cold is the air when the wind blows any thing strong.

It is not a little surprising to many, that such extreme cold should be felt in these parts of America, more than

Reason of the cold being more intense in North America, than at places under the same parallel of latitude in Europe.

places of the same latitude on the coast of Norway; but the difference I take to be occasioned by wind blowing constantly here, for 7 months in the 12, betwteen the N. E. and N. W. and passing over a large track of land, and exceeding high mountains, &c. as before-mentioned. Whereas at Drontheim in Norway, as I observed some years ago in wintering there, the wind all the winter comes from the N. and N. N. W. and crosses a great part of the ocean clear of these large bodies of ice we find here perpetually. At this place we have constantly every year 9 months frost and snow, and insufferable cold from October till the beginning of May.

Account of Icebergs, or islands of ice on the coast of North America.

The vast bodies of ice we meet with in our passage from England to Hudson's Bay, are very surprising, not only as to quantity, but magnitude, and as unaccountable how they are formed of so great a bulk, some of them being immersed 100 fathoms or more under the surface of the ocean, and one-fifth or one-sixth part above, and three or four miles in circumference. Some hundreds of these we sometimes see in our voyage here, all in sight at once, if the weather is clear. Some of them are frequently seen on the coasts and banks of Newfoundland and New-England, though much diminished.

When I have been becalmed in Hudson's Straits, for three or four tides together, I have taken my boat and laid close to the side of one of them, sounded and found 100 fathom water all around it. The tide floweth here above four fathom; and I have observed, by marks upon a body of ice, the tide to rise and fall that difference, which was a certainty of its being aground. Likewise, in a harbour in the island of Resolution, where I continued four days, three of these isles of ice (as we call them) came aground. I sounded along by the side of one of them, quite round it, and found thirty-two fathom water, and the height above the surface but ten yards; another was twenty-eight fathom under, and the perpendicular height but nine yards above the water.

Manner in which they are formed.

I can in no other manner account for the aggregation of such large bodies of ice but this: all along the coasts of Straits Davis, both sides of Baffin's-bay, Hudson's Straits, Anticosti, or Labradore, the land is very high and bold, and 100 fathoms, or more, close to the shore. These shores have many inlets or fuirs, the cavities of which are filled up with ice and snow, by the almost perpetual winters there, and frozen to the ground, increasing four, five or seven years, till a kind of deluge or landflood, which commonly happens in that space of time throughout those parts, breaks them loose, and launches them into the straits of the ocean, where they are driven about by the variable winds and currents in June, July, and August, rather increasing than diminishing in bulk, being surrounded (except in four or five points of the compass) with smaller ice for many hundred leagues, and land covered all the year with snow, the weather being extremely cold, for the most part, in those summer months.

The smaller ice that almost fills the straits and bays, and covers many leagues up the ocean along the coast, is from four to ten fathoms thick, and chills the air to that degree, that there is a constant increase to the large isles by the sea's washing against them, and the perpetual wet fogs, like small rain, freezing as they settle upon the ice; and their being so deeply immersed under water, and such a small portion above, prevents the winds having much power to move them: for though it blows from the north-west quarter near nine months in twelve, and consequently those isles are driven towards a warmer climate, yet the progressive motion is so slow, that it must take up many years before they can get 500 or 600 leagues to the southward; I am of opinion some hundreds of years are required; for they cannot, I think, dissolve before they come between the 50th and 40th degree of latitude, where the heat of the sun consuming the upper parts, they lighten and waste in time: yet there is a perpetual supply from the northern parts, which will so continue as long as it pleases the Author of all beings to keep things in their present state."

Professor Leslie's theory of the formation of Icebergs.

A new and ingenious theory of the formation of these huge masses of ice has been recently given by Professor Leslie. As this explanation is founded on the result of a very curious experiment, we shall make no apology for giving a full account of it in Mr Leslie's own words.

"When very feeble powers of refrigeration are employed, a most singular and beautiful appearance is in course of time slowly produced. If a pan of porous earthen-ware, from four to six inches wide, be filled to the utmost with common water till it rise above the lips, and now planted above a dish of ten or twelve inches diameter, containing a body of sulphuric acid, and having a round broad receiver passed over it; on reducing the included air to some limit between the twentieth and the fifth part of its usual density, according to the coldness of the apartment, the liquid mass will, in the space of an hour or two, become entwined with icy shoots, which gradually enlarge and acquire more solidity, but always leave the fabric loose and unfrozen below. The icy crust which covers the rim, now receiving continual accessions from beneath, rises perpendicularly by insensible degrees. From each point on the rough surface of the vessel, filaments of ice, like bundles of spun glass, are protruded, fed by the humidity conveyed through its substance, and forming, in their aggregation, a fine silvery surface, analogous to that of fibrous gypsum or satin-spar. At the same time, another similar growth, though of less extent, takes place on the under side of the pan, so that continuous icy threads might appear vertically to transpierce the ware. The whole of the bottom becomes likewise covered over with elegant icy foliations. Twenty or thirty hours may be required to produce those singular effects; but the upper body of ice continues to rise for the space of several days, till it forms a circular wall of near three inches in height, leaving an interior grotto lined with fantastic groupes of icicles. In the meanwhile, the exfoliations have disappeared from the under side, and the outer incrustation is reduced, by the absorbing process, to a narrow ring. The icy wall now suffers a regular waste from external erosion, and its fibrous structure becomes rounded and less apparent. Of its altitude, however, it loses but little for some time; and even a decomposition of congealed films along its coping or upper edge, seems to take place at a certain stage of the process. This curious effect is owing to a circumstance, which, as it serves to explain some of the grand productions of nature, merits particular attention. The circular margin of the ice, being nearer the action of the sulphuric acid than its inner cavity, must suffer, by direct evaporation, a greater loss of heat; and consequently each portion of thin air that rises from the low cavity, being chilled in passing over the colder ledge, must deposit a minute corresponding share of its moisture, which instantly attaches itself and incrusts the ring. Whatever inequalities existed at first in the surface of the ice, will hence continually increase.

This explication seems to throw some light on the origin of those vast bodies of ice which occur within the Arctic Circle, and which, towering like clustered peaks above the surface of the ocean, have received the name of *icebergs.* They frequently project above an hundred feet, and must therefore have ten times as much depth concealed under water. To suppose them to have been detached from a solid field of such tremendous thickness, would seem utterly improbable. It may indeed be doubted, whether any part of the ocean be ever naturally frozen. The ice which I have formed from salt water by the frigorific process, was always incompact, inclosing brine within its interstices, and resembling the aspect of what is called water-ice, or dilute syrup congealed. Perhaps an extremely slow congelation, descending regularly from the surface, may press down the saline particles, which are never absolutely detached from the water, and thus force them to combine more largely with the mass below. But even admitting this idea, it would be still required to account for the great elevation of those icy cliffs. The most satisfactory mode, probably, of explaining the phenomenon, is to refer it to the operation of a general principle, by which the inequalities on the surface of a field of ice must be constantly increased. The lower parts of the field, being nearer the tempered mass of the ocean, are not so cold as those which project into the atmosphere, and consequently the air which ascends, becoming chilled in sweeping over the eminences, there deposits some of its moisture, forming an icy coat. But this continued incrustation, in the lapse of ages, produces a vast accumulation, till the shapeless mass is at length precipitated by its own weight.

Other natural phenomena will receive illustration from the facts disclosed by the refrigerating process. In the rigorous climes of the north, the alternations of the seasons are most rapid. On the approach of spring, the thick fields of ice which, in Russia or Canada, cover the Neva or the St Lawrence, break up with overwhelming fury, accompanied too by tremendous explosions. Nor is this noise to be ascribed to the mere crash of the falling fragments. In those frightful climates, the winter at once sets in with most intense frost, which probably envelopes the globules of air separated from the water in the act of congelation, and, invading them on all sides, reduces them to a state of high condensation. When the mild weather begins, therefore, to prevail, the body of ice, penetrated by the warmth, becomes soft and friable; and the minute but numerously interspersed globules of imprisoned air, exerting together their concentrated elasticity, produce the most violent explosive disruptions."

COLDENIA, a genus of plants of the class Tetrandria, and order Tetragynia. See BOTANY, p. 127.

COLEUS, a genus of plants of the class Didynamia, and order Gymnospermia. See BOTANY, p. 256.

COLERAINE, a market and borough town of Ireland, in the county of Londonderry. It is situated upon the river Bann, about three miles above its mouth, and is a tolerably large town. Considerable sums of money have been fruitlessly expended on the harbour of Coleraine, but it is merely a bar harbour, and will admit only vessels of a small burden at the time of high water. The salmon fishery at Coleraine is one of the two largest in Ireland. It belongs to the London Society, who have leased it to Irishmen, by whom it is again let at a considerable advance of rent, to a company who keeps fast sailing vessels, for the purpose of conveying the fish to Liverpool and other places. In 1796, the salmon sold at 3d. per pound, and in 1808, it was as high as 1s. 2d. Mr Wakefield visited the famous salmon leap within a mile of Coleraine, and observed the salmon springing from the water in hundreds. In 1776, about 1400 were caught at one haul.

There is also an eel fishery at Coleraine belonging to Lord Donegal, which lets at £1000 per annum; the eels are sold at 4d. per pound. The burgh of Coleraine belongs to the London Society, but the Beresford interest returns the member. The annual duties of this harbour amounted to £6000 in 1801. Population 4500. (*j*)

COLLINS, WILLIAM, an ingenious English poet, was born in 1720 at Chichester, where his father carried on business as a hatter. He was educated on the foundation of Winchester, but missed the advantage annexed to that institution, of going off to a fellowship in New College, Oxford, as no vacancy occurred while he continued within the limited age. He went notwithstanding to Oxford, where he was first entered of Queen's College, and afterwards of Magdalen's, but remained only till he took the degree of Bachelor of Arts. Like many other poets, Collins seems to have delayed his choice of a profession till the time for chusing was past. It unfortunately happens, that the age at which this important decision should be made, is the same at which men of genius begin to discover their intellectual superiority, and in the triumph which this discovery creates, they think themselves entitled to a higher destiny than that of their companions, who content themselves with occupations requiring no unusual portion of ability. They are thus tempted to cherish indistinct though splendid visions of ambition, without calculating exactly the steps by which it is to be gratified, and they reject the employments for which they were intended, from no decided preference of any other, but from a hope that, to make their genius known, will be all that is necessary for advancing them to an eminence, which no success in an ordinary profession could confer. Such appears to have been the case with Shakespeare and Spenser, with Milton and Dryden, with Thomson and Gray, and with Chatterton and Cowper; and of all our poets, none have been richer in that originality of genius, which distinguishes its possessor from the rest of his species, than those whom we have named. This seems likewise to have been the case with Collins, whose success in college exercises seduced him into so early an application to poetry, that, before he quitted the university, he had published his Oriental Eclogues. Though the demand for these was not such as testified any extraordinary portion of public favour, yet having acquainted their author with the delight of doing that which can be done by few, and probably given him sufficient confidence in his powers, he hastened from Oxford, before the usual period of attendance was completed, to procure wealth and fame in London by his pen. His scheme, however, seems not to have been arranged with much precision, and instead of engaging in any important work, he frittered away his time in desultory exertion, designing what he never executed, and executing what he had never designed. Literary adventurers have generally been destined to a life of discomfort and perplexity; nor was Collins an exception to the common lot. Having no regular employment, he had no regular income. When pressed by the prospect of want, he resolved on diligence, but when the pressure was removed, his resolutions were forgot. Amid this fluctuation, instead of writing a history of the revival of letters, of which he frequently talked, or entering on various dramatic works, which were among the number of his projects, he contented himself with the production of a few Odes, which he seems to have composed for recreation rather than emolument. These Odes, however, abound in excellencies, to which genius alone could give existence; and justify a belief, that the uniform tranquillity derived from easy circumstances, is less propitious to the loftier flights of imagination, than the transient elasticity of spirits, which the sudden suspension of disquiet has a natural tendency to produce. Professional writers in a great city, are generally addicted to conviviality. Requiring a relaxation from labour, they prefer those evening clubs, where they meet with persons who are in a condition similar to their own, and by whom that colloquial power which they derive from their endowments, their acquirements, and their mode of life, is both excited and admired. In these assemblies of contemporary wits, Collins became acquainted with Johnson, who, says the poet, was of "a decent and manly appearance, his knowledge considerable, his views extensive, his conversation elegant, and his disposition cheerful." It was natural that a sympathy should arise between such minds as those of Collins and Johnson, while both were equally depressed by pecuniary difficulties, and elevated by a consciousness of superiority to the wealthy crowd who permitted them to starve, but over all of whom they knew themselves destined to rise, by the interest they were to create, and the renown they were to obtain. They accordingly grew into habits of such confidential intimacy, that, when the poet was skulking from an officer on the watch to arrest him, Johnson, whom he knew to be in no great security from a similar humiliation, was readily admitted to his retreat. From this embarrassment, he was relieved by a small sum which the booksellers were persuaded to advance, on his promise of writing for them a translation of Aristotle's Poetics, with a commentary. He then retired to the country, but soon after returned to town, on succeeding to a legacy of £2000, which had been left him by an uncle, and out of which he immediately relieved himself of his debt to the booksellers. This succession, to one who had been so long accustomed to indigence, appeared an inexhaustible fortune; but Providence did not permit him to enjoy it, for as he improved in circumstances, he declined in health. The malady into which he sunk, is described by Johnson as a species of insanity; but this description is afterwards qualified by a more minute detail of its symptoms, from which we are left to conclude, that it was rather nervous debility than mental derangement. "His disorder," says the biographer, "was not alienation of mind, but general laxity and feebleness, a deficiency rather of his vital than intellectual powers. What he spoke wanted neither judgment nor spirit; but a few minutes exhausted him, so that he was forced to rest upon the couch, till a short cessation restored his powers, and he was again able to talk with his former vigour. The approaches of this dreadful malady he began to feel soon after his uncle's death; and with the usual eagerness of men so diseased, eagerly snatched that temporary relief with which the table and the bottle flatter and seduce. But his health continually declined, and he grew more and more burthensome to himself." When Collins perceived this partial failure of his faculties, for a consciousness of his case seems to have been its most distressing effect, he was advised to travel, that he might divert his mind from pondering on its own decay. He therefore went to France, but as the experiment did not succeed, he speedily returned, and was for some time confined in a madhouse. He afterwards put himself under the care of a sister in Chichester, where he died at the early age of 36. It is pleasing to learn from his illustrious friend, that, amid all his afflictions, no fretfulness of spirit impelled him to abandon the endeavour of soothing them by religion. When Johnson visited him on his return from France, and found a New Testament in his hand, "I have only one book," said Collins, "but that is the best." He was buried in the cathedral of Chichester.

Of men who, like Collins, have led a life of adversity, it is proper to judge with indulgence. Many whose lot has been smooth and easy, like tempers which have never been tried, enjoy a favour and reputation which, in harsher circumstances, they would soon have forfeited; and he whose aberrations of conduct were few, when his virtue could produce no temporal advantage, may obtain credit for the superior rectitude he would have exhibited, had he been encouraged by a prospect of its usual rewards. Collins in his better days, does not seem to have exceeded the dissipation of his lettered associates; and the attic orgies, which were graced by the wisdom, and guarded by the virtue, of a Johnson, could be no matter of serious reproach. If the horrors of mind in which he was afterwards plunged, drove him to indulgences of a less venial description, the anguish of the disease may plead some pardon for the desperate remedy, by which he solicited its momentary abatement; and it is no slender praise, that for his practical errors he never sought theoretical apologies, but preserved the soundness of his principles, under the strongest temptations to quiet self reproof by relaxing them.

The genius of Collins may be classed among those of the higher order. Like Gray, he has left few productions, yet by these we may calculate the powers from which they proceeded, as by a small segment we can measure the dimensions of the whole circle. In the effusions of Collins we find every thing surveyed with the eye, and touched by the hand of a poet. He does not, like most of the polished versifiers who immediately preceded him, present elegant imitations of nature, under those aspects, in which she must appear to all observers. He views her through the prism of a glowing imagination, and transfers to her the colours which that faculty supplies. A common artist may be abundantly dextrous in his portrait of visible forms, but it is only a master, like Lorraine, who can enrich his landscape with hues which are drawn from his own ideal stores of beauty, which are characteristic of himself alone, and which stamp on his works the impression of original genius. Collins appears entitled to similar praise. Even in his Oriental Eclogues, though juvenile productions, which his maturer taste is said to have despised, the warmth of scenery which they display, and the tropical lassitude which they seem to breathe, shew the early vivacity of his conceptions; while his Odes excel in a peculiar richness of personification, and in the creations of a generative fancy, which impregnates all its objects with life and intellect. It must be acknowledged, indeed, that he sometimes carries his favourite style to excess, and continues to crowd the scene with visionary beings, or, in his own words, "with all the shadowy tribes of mind," till, by losing their distinctness, they lose their interest. His ideas, too, are occasionally so remote from that ordinary train of thought, to which the resources of ordinary language are, in some measure, limited, that while straining to express them, by means unequal to the end, he becomes at times unmusical and incorrect, and more frequently obscure. The best of his works are not entirely free from these faults. In the *Ode to the Passions*, which is perhaps the most popular of them all, we find the following offensive change from the singular pronoun, to the plural, in its singular use.

> " Why, goddess, why, to us denied,
> Lay'st thou thy antient lyre aside?
> As in that lov'd Athenian bower
> *You* learn'd an all commanding power,
> *Thy* mimic soul, O nymph endear'd," &c.

Our praise of Collins may, perhaps, appear extravagant, especially to those who adopt the fastidiousness of Johnson; but we appeal from this opinion, to the judgment of the public, already pronounced. A lofty place, in the temple of genius, can scarcely be denied to him, whose " gifted mind" had the power of producing compositions, so often read, rehearsed, and sung, as the *Odes to Evening; to the Passions;* and *to the Memory of those who died in* 1745. Nor should we forget the *Dirge in Cymbeline*, and the *Verses on the Death of Thomson*, which breathe the genuine spirit of sweetness, pathos, and simplicity. If a short fragment can preserve for Sappho a station among the higher rank of poets, we may offer these Odes as a standard to which the poetical energy of Collins was qualified to rise, notwithstanding his occasional inequality in its exertion. (w)

COLLISION. See MECHANICS.

COLMAR, a town of France, and the capital of the department of the upper Rhine, is situated at the junction of the Fecht and the rivulet Lauch, about half a league from their confluence with the Ill. The town stands on a fine plain near the foot of a mountain, and is reckoned one of the most agreeable and healthy places in the country. Colmar is surrounded with a wall, flanked with towers, and its streets are kept remarkably clean, by a number of small canals from the Fecht and the Lauch. It carries on a considerable trade in corn; and the wines of the adjacent country are exported in considerable quantities. At a little distance from the town there is a powder mill, and there are manufactures of woollen cloths, calico prints, stockings, hardware, &c. Population 13,396. East Long. 7° 22′ 11″, North Lat. 48° 4′ 44″. (*w*)

COLOGNE, the *Colonia Agrippina* of the ancients, is a town of France, and capital of the department of the Roer, is situated on the left bank of the Rhine, and is of a semicircular form, having its concavity towards the river. In 1187, Philip, archbishop of Heinsberg, took down the old walls of Cologne, and built those with which it is at present surrounded. These walls, which are now in a ruinous state, have 83 towers with conical roofs, 13 principal gates, and a circumference of 10,326 yards, or nearly 6 miles.

The streets, which are all paved with basalt, are narrow, winding, and gloomy, particularly those near the Rhine, which are crowded together for the purposes of commerce. The houses are very high, old, and ruinous, and form a singular mixture of all stiles of building during the last 1000 years. There is now, however, a very considerable number of modern houses. The materials for building are very expensive, being brought from a considerable distance, and the Dutch stile generally prevails.

The principal squares at Cologne, are the old market, the hay market, and the new market. The last of these is very extensive, and contains a beautiful promenade under a double row of lime trees. The chief streets, are the *Rue Large*, the *Rue St Jean*, the *Rue des Apostres*, the *Rue de Sexenhauser*, the *Trankgass*, and the large street, which extends from the gate of St Severin to that of Eichelstein.

One of the principal edifices in Cologne is the cathedral church of St Peter's, which was begun in 1248, by the elector Conrad, but remains still an unfinished ruin. Had the design been carried into execution, it would have formed one of the finest and most stupendous Gothic edifices in Europe, and even as it stands at present, overgrown with grass, and mouldering away with age, it presents a spectacle of unexampled sublimity. In the original plan, the two towers were each to have been 500 feet in height; one of them is only raised 21 feet above the foundation, and the other is no higher than 150 feet, and upon the top is still to be seen the crane by which the stones were raised. The body of the cathedral is very large. It is divided by four ranges of columns, amounting to 100, and the four middle ones are no less than forty feet in circumference. Behind the principal altar, which has a most imposing effect, is the chapel of the three kings, which the elector Maximilian built of marble. It contains the bodies of the three kings, and of the martyrs Felix, Nabor, and Gregory of Spoletto. In the year 1789, before the French revolution, the tombs were adorned with diamonds, and precious stones of all kinds, and 226 pieces of antiquity, and was reckoned the most superb and rich monument in Europe; but we fear, from the silence of recent travellers, that these spoils have been carried to Paris. A full account, however, of the tombs, and of all their ornaments, is preserved in a work entitled *Collection des pierres antiques dont la caisse des saints trois Rois Mages est enrichie dans l'eglise metropolitaine a Cologne, gravées apres leur empreintes, avec un discours historique analogue*, par. J. P. M. N. Bonn, 1781. The cathedral was used as a granary in 1800.

Next to the cathedral in importance and antiquity is the chapter of the ladies of *St Marie au Capitole*. The church is vast and well illuminated, and appears to have been built in the eighth century. The chapter of St Gereon is very rich and fine. The church, which was built in the eleventh century, has a vast cupola, and is reckoned the finest in Cologne. The chapter of St Ursula, which is filled with the bones of 11,000 virgins, is very ancient. In the choir of the church is a painting representing St Ursula arriving at Cologne, with a numerous attendance, in a large ship of war. The other chapters are those of St Severin, St Cunibert, of the Mere de Dieux à Staffeln, of St Andrew, of St George, of the Apostles, and of St Cecilia. At one time Cologne is said to have contained 260 churches and 37 convents.

The arsenal, which is used also as a kind of granary, is remarkable only for its size. It contains a great quantity of ancient arms, and is in a state of rapid decay. The theatre was built in 1783, but is far from being an elegant building. There are no fewer than twelve hospitals in Cologne, a society of emulation, a central school, a botanical garden, a physical cabinet, and a library in which are preserved the original letters of the Marshal de Turenne.

A large flying bridge serves as a communication between Cologne and Deutz on the right bank of the Rhine.

A very considerable trade is carried on in this city. It is the centre of all the commerce on the Rhine; it exports the wines of the Rhine and the Moselle, cast-iron goods of all kinds, timber for the purposes of ship-building, pottery goods, and slates. Its principal imports are coals from the adjacent countries, spiceries of all kinds, dry and salted fish, particularly herring, oils of every kind, and all sorts of woollen and silken stuffs. The principal manufactures of this town are cotton cloths, ribbands, paper, stockings, lace, and tobacco. About four leagues from Cologne, in the neighbourhood of Bruhl and Liblas, are mines of tuffa, known by the name of the brown earth of Cologne, which is used as a water colour by painters. It contains more vegetable than mineral matter, and probably has been produced by pieces of wood that have been long buried in the earth. The number of houses in Cologne is 7,404, and the population 38,844. East Long. 6° 55′ 15″, and North Lat. 50° 55′ 21″. A plan and elevation of the cathedral of Cologne, according to the original designs, and the most minute particulars respecting the history and antiquities of the town, will be found in the *Voyage sur le Rhin, depuis Mayence jusqu' a Dusseldorf,* tom ii. p. 88. Neuwied. 1791. (*)

COLONSAY. See HEBRIDES.

COLONY.

Definition.

COLONY (Latin *colonia,* Greek *ἀποικία*) signifies a body of settlers removed to a distance from their native country. In early ages, when agriculture formed almost the sole object of productive industry, a change of this description was accounted applicable to those only who might be induced to remove for the purpose of tillage. Hence the derivation of the Latin name *colonia* from *colo.* That name has passed into most European languages, although the more general and comprehensive term in Greek, would have been the fit appellation of modern settlements, many of which were formed with other views than those of agriculture. We shall proceed to treat at some length of the history of colonies, particularly those of modern times, and shall, for the sake of perspicuity, arrange the multiform details of the subject under specific heads.

Ancient colonies.

Ancient Colonies.—The earliest colonies of which the history is authenticated, were those of Greece. They owed their origin, neither to schemes of conquest, nor to speculations of commerce, but to the plain and direct conviction of the impracticability of subsisting in the territory of the mother country. Though Greece, in her best days, had by no means a population beyond the resources of her soil when tolerably cultivated, the art of tillage was, in the early ages, so rude and unproductive, as to impress the inhabitants with the belief, that the alternative of expatriation was indispensible. Of the manner of conducting those early emigrations, we have no regular accounts; they are known chiefly by the rapid progress which the settlements had made at the beginning of the ascertained period of Grecian history. By this time colonies of Dorians had been long established in Italy and Sicily; while those of the Ionians and Æolians had occupied the Islands of the Ægean Sea and the maritime part of Asia Minor. It was in these distant settlements that the early philosophers, poets, and political sages of Greece made their appearance. So quick an advance in improvement affords a remarkable example of a truth to which we shall presently advert—the striking advantages of a colonial establishment in facilitating the progress of arts and sciences. In the case of the Greeks, these advantages were not counteracted by any assumption of controul on the part of the parent state. An amicable intercourse was kept up between the kindred tribes, but the colony was neither involved in the wars of the mother country, nor restricted from making her separate interest the object of all her political arrangements. The formation of these colonies arose, as in the case of our American settlements, less from the act of governments, than from the enterprize of individuals. This circumstance, joined to a distance, which, small as it was, formed, in the infancy of navigation, a serious obstacle to the maintenance of intimacy of connection, rendered the colonies almost always independent of the mother country. When Cyrus overran the Lydian territory, the parent states in Greece declined to take arms in defence of their kindred tribes along the coast of Asia Minor. The latter were accordingly incorporated with the Persian monarchy, and remained subject to it, until the overthrow of Xerxes, and the naval triumphs of Cimon, enabled the Greeks to demand the acknowledgment of their independence, as a condition of suspending hostilities. During the preceding æra of Grecian glory, the colonies resumed, or rather formed for the first time, an alliance with Athens, the chief maritime power of the mother country, and contributed an annual sum as a fund for the general defence against Persia. This alliance continued till the latter part of the Peloponnesian war. The most important point in it for our present consideration, is the fact that the alliance in question comprehended, not merely the settlements of Athens, but those of her rival states, and was posterior, by several centuries, to the original emigration. It arose, therefore, less from the recollections of early connection, than from the dictates of present policy.

The Roman colonies were, in several respects, different from those of Greece. After the abrogation, in the third century of Rome, of the laws which stipulated the division of the conquered lands among the military citizens, the middling classes among the Romans were frequently losers even by successful war. Their limited portions of property were often neglected during their absence in the field, while their richer neighbours were enabled to carry on an uninterrupted cultivation by the labour of slaves. Hence the embarrassed circumstances and immense debts of the plebeians, by whom we are to understand, not the vulgar, but the middling classes in Rome. Hence those reiterated discontents, and the frequent clamour for the enactment of an Agrarian law. After many struggles, a law was at last passed to prohibit the possession of more than five hundred jugera, (three hundred and fifty English acres) by any individual; but the execution of this law was found impracticable, and from the influence of the rich over the poor, an attempt on the part of a spirited citizen to enforce it, seldom failed to lead to his downfall.* The usual salvo, on occasions of serious discontent, was an offer by the patricians to lead forth a new colony, that was to divide a remote portion of lately conquered land among a specified number of needy citizens. These settled on the allotted spot for the purpose (agreeably to the name *colonia*) of cultivating it; but the military policy of Rome made these detached portions of the community subservient likewise to other objects. The transplanted citizens were soldiers, and formed a strong out-post for the defence of the territories between them and the parent city. This system of colonization, exercised at first on a small scale, and directed chiefly against those troublesome neighbours of Rome, the Æqui and Volsci, was progressively extended, and continued even after the fall of Roman liberty. Among other colonies, it is on record that Julius Cæsar led one to Carthage. No fewer than 164 colonies were successively established within the limits of Italy, in the period between the foundation of the city and the death of the Emperor Augustus.

---

* Brodie's *History of the Roman Government,* passim.

It does not appear, that any of the Roman colonies gave evidence of a progress remarkably superior to that of old settled states. This inferiority to the Grecian settlements, may be ascribed, partly to the almost exclusive attention of the parent state to military affairs, and more perhaps to the circumstance of the Roman establishments taking place in districts already occupied and cultivated. The new settlers were consequently incorporated with the mass of former inhabitants, and were more likely to imbibe their manners than to succeed in introducing those habits of economy and exertion, which, in general, are characteristic of emigrating citizens. The Roman colonies have some resemblance to the Indian settlements of modern Europeans. The native population predominating greatly over the new comers, the latter are to be considered in the light of a garrison to an out-post, maintained for the benefit of the mother country.

Carthage, approaching in her policy, much more than any other ancient state, to the habits of the maritime powers of modern times, we are enabled to trace a correspondent resemblance in her colonies. There is no reason to assign their origin to scarcity of subsistence at home, since the fleets and treasures of Carthage could, without difficulty, import an abundant supply of corn. Her colonies, therefore, seem to have been military stations, chosen for the purpose of commanding tribute, or appropriating the commerce of a particular district. The two mercantile treaties between Carthage and Rome, preserved by Polybius, imply an earlier attention on the part of the Romans to maritime affairs, than is commonly imagined. On the part of the Carthaginians, these curious documents discover a mercantile jealousy, which strongly reminds us of the prevalence of the same feelings in our own days.

Modern colonies.

Modern Colonies.—The Gothic ages, unfavourable to every kind of improvement, have nothing to boast of in respect to colonies. The crusades, though conducive, in several respects, to the removal of European barbarism, appear to have led to few useful establishments of the kind which we are now discussing. We meet accordingly with no examples of colonization, sufficiently general to mark an æra in history, until the comparatively recent discoveries of America, and of a passage to India by the Cape of Good Hope. It is fully three centuries since the progressive extension of the labours of the leading navigators opened the East and West to the enterprise of colonists from Spain and Portugal. India, the imagined depot of incalculable wealth, was the common object of the voyagers of either country. Columbus, sufficiently instructed, even in that illiterate age, to be convinced of the spherical form of the earth, calculated that the longer the distance to India was by an eastward course, the shorter it would be by the west. This argument formed the ground-work of his various applications to maritime powers for the equipment of a suitable squadron; and, in defence of any miscalculation on his part, it is proper to state, that the distance of India to the east had been magnified, beyond all bounds, by the reports of travellers. It was in consequence of India being uppermost in the thoughts of Columbus and other navigators, that the name of *West Indies*, or, as the French call them the *Little Indies*, was given to the Windward and Leeward Islands; and the appellation of Indians, bestowed, in the most comprehensive sense, on the savage aborigines of the immense continent of America.

The boldness and perseverance of Columbus, have, in connection with the selfish conduct of the court of Spain, after the death of his royal patroness Isabella, procured for him a large share of public sympathy, and have made the politic part of his proceedings attract a smaller portion of attention. He displayed, however, all the thoughtfulness of an Italian, along with that activity and power of rendering circumstances subservient to his plans, which characterise the authors of great enterprises. He continued to give the name of India to his discoveries, after it became perfectly clear that the two countries had nothing in common; and he made, in a public procession, a splendid parade of the gold and the products imported from these new regions. By way of interesting the Spanish government in the labour of the mines, he proposed, that no less than half the metallic treasures found in them should belong to the crown. This proportion was soon found exorbitant, and progressively reduced to a third, a fifth, a tenth, and eventually to a twentieth. The precious metals were long the sole object of attraction to the emigrants from Spain; to settle in their new territories with a view to cultivation, being for many ages foreign to their thoughts. The Portuguese, likewise, pursued mineral and metallic treasures in India, and the difference of conduct in the two nations, proceeded less from a diversity in their plans or intentions, than in the power and civilization of the countries which they respectively invaded. Mexico and Peru, defended by a feeble and unskilful race, offered little resistance to bands of enterprising adventurers; while India and her islands possessed sufficient population to call forth all the courage and exertion of the Portuguese commanders.

The motives which led to the establishment of the Spanish and Portuguese colonies, were thus considerably different from those which actuated the Greeks and Romans. There was here no complaint of deficient subsistence at home; no necessity to separate one portion of the population to serve as an outpost to the rest. In the case of India, the hope of a lucrative traffic; in that of America, the expectation of valuable mines supplied the decisive impulse to emigration. Nearly a century elapsed before either Spain or Portugal encountered serious opposition in their new territories. Portugal, in consequence of the encouragement of navigation by the government, and Spain by the absorption of so many maritime provinces under the sovereignty of Charles V. and Philip II., had taken decidedly a lead in the naval affairs in Europe. France, torn by internal dissension, and better fitted by situation for inland than foreign commerce, was no formidable competitor; and England was only beginning to feel her own strength. At last, the long continuance of good government under Queen Elizabeth, and the discomfiture of the Spanish armada, opened to our countrymen the prospect, not merely of annoying the Spaniards in the western hemisphere, but of appropriating a portion of these regions in permanent occupancy. Still the schemes of the intended colonists were directed much more to the search of gold and silver, than to the cultivation of the soil. It was very generally believed, that there existed, in unknown parts of America, veins of gold and silver, as abundant as those of copper or iron in Europe. Hence credit was given to the tales which led Gonzalo, Pizarro, Orellano, and others from Peru to the inhospitable tracks along the river Amazons; hence, likewise, the avidity in this country to believe Sir Walter Raleigh's fiction of the kingdom of El Dorado, and of a chief, whose throne was made of solid gold. These deceptions were propagated and continued, years after years, from a solicitude, on the part of the oppressed Americans, to send forward their troublesome visitors to a distant region. (Southey's *Brazil*, vol. i.) Accordingly, it was not until the seventeenth century, that our countrymen began to settle as cultivators, either in the West Indies or North America. To the Dutch, an opportunity of aggression on the Portuguese settlements in the East and West was opened, by the assumption of the crown of Portugal by their mortal enemy, Philip II. That step gave rise to long continued warfare in Brazil, and to a series of exploits in the Indian seas, which laid the foundation of very extensive conquests.

We shall now proceed to treat, in succession, of the several colonial settlements of European powers, observing, in the outset, that the working of mines has not been prosecuted in any other settlements than those of Spain and Portugal. That the want of those dazzling attractions is very far from being a disadvantage, will be sufficiently apparent, when we come to treat, in the sequel of our work, of the nature of mines. Human industry cannot be applied to a more precarious pursuit; and it is a well known fact, that, poorly cultivated as are Brazil, Mexico, and Peru, there is infinitely more comfort among the inhabitants of the agricultural than of the mining districts of these countries.

Spanish colonies.

Spanish Colonies.—The history of the transatlantic possessions of Spain, affords a most striking example of the evils of monopoly. All European nations have erred in this respect, and have injured themselves accordingly; but the sum total of their trespasses is trifling when put in comparison with those of the Spanish government. To put colonial trade into the hands of an exclusive company, is to create a body of which the interest is in direct opposition to that of the colony. Instead of favouring the progressive advance of consumption and production, the object of the company is to make sure, by a very plain process, of their personal profit at the expence of both. Abroad, the company's profit is obtained by limiting the supplies exported from the mother country; at home, by limiting the imports from the colony. The Spanish government was wholly ignorant of the principles of trade, and wonderfully jealous of the entrance of foreigners into their transatlantic possessions. It continued, until very lately, under the delusion, that the grand advantage of Mexico and Peru consisted in their mines, and that no pains should be spared to prohibit the access of such individuals as were not employed by government, to these mysterious deposits. It was determined, therefore, to confine the American trade to a single harbour, and, during several ages, Seville was the favoured port. It was not till 1720, two centuries after the occupation of America, that the privilege of colonial trade was extended to Cadiz. Even then, no person was allowed to ship an article of goods for Spanish America without a licence from the exclusive managers of the trade. These managers conducted their affairs with all the confidence and supineness of men assured of an uninterrupted possession of the colonial commerce. The vessels for Peru, Chili, and Terra Firma, were called galleons, and sailed only once a year. Mexico and the northern provinces were supplied by what was called the flota, which sailed in a collective shape only once in three years. No foreigner, and even no Spaniard, embarked on board these vessels without the permission of government; and, in the passage, the fleets were prohibited from touching at any intermediary port. But this was not all; the American colonies were strictly interdicted from holding a commercial communication with each other. Caraccas, for example, could receive no supplies from the neighbouring island of Trinidad, nor could Mexico relieve its wants by an application to the southern colonies. In short, the merchants were prevented from transacting business except at prescribed seasons, and at a few specified seaports. These were for the continent, Carthagena, with the unhealthy towns of Porto Bello, and Vera Cruz; in Cuba, the less exceptionable station of the Havanna, which, from the excellence of its harbour, and its central position, was the appointed rendezvous of all homeward bound fleets. Under such a system, we need not wonder that Robertson's *History of America*, cautiously and temperately as it is written, was not permitted to obtain circulation in Spain. The Royal Academy of History, at Madrid, unanimously elected him one of their members in 1777, in testimony of their approbation of his work, and appointed a gentleman to translate it into Spanish; but after considerable progress had been made in the translation, the Spanish government, dreading the publication of a work which so fully explained the nature of the trade with America, and the system of colonial administration, interposed its authority to stop the undertaking. See Mr Stewart's *Life of Dr Robertson*.

The consequence of cramping, in such a manner, the intercourse between the mother country and the colonies, was an exorbitant enhancement of the articles exported, it being common to charge in America double, and sometimes triple, the European price. That intelligent traveller, Ulloa, relates, that he has seen a pound of iron currently sold in Peru at four shillings and sixpence, and the pound of steel for six shillings and ninepence sterling. Such a state of things could not fail to lead to smuggling. Accordingly, all the exertion, the expenditure, and the rigour shewn, age after age, by the Spanish government, were ineffectual in preventing the existence of a clandestine intercourse of great extent. One penal law was added to another, and even spiritual punishment, the most formidable of all punishments to a Spaniard, was threatened; but the wants of the colonists, and the vast extent of accessible coast, had the effect of counteracting all impediments. It was a singular circumstance, that the English contraband traders in Jamaica were supposed to enjoy as much of the Spanish colonial trade as the mother country herself; and the consequence was a progressive diminution of the regular shipments from the latter, until at last they threatened to fall off altogether.

The mortifying evidence of experience led ultimately to a gradual modification of this absurd monopoly. In 1740, the Spanish government consented to the use of "register ships," which may be defined "separate equipments, unconnected with the periodical fleets, and less limited in regard to freedom of intercourse with the colonial seaports." This, however, produced hardly any other good effect than an increased frequency of exportation, for a heavy tax was exacted by government on the register cargoes, as well in the shape of license as of duty. It was not till 1764 that regular packets were established between the colonies and the mother country. These packets sailed from Corunna, and were allowed to carry both out and home limited investments of merchandise. Next year, a more important step was taken, the intercourse with the Spanish West India islands being laid open to the principal ports of Spain. A few years after, a similar permission was granted in regard to Louisiana, Yucatan, and Campeachy. But it was withheld till 1778 from the richer colonies of Peru, Chili, Buenos Ayres, Santa Fé, and Guatimala. Last of all came Mexico, which, partly from its superior importance in respect of mines, partly perhaps from an apprehension of internal dissatisfaction, was not opened to the principal ports of the mother country until 1788. The ports thus licensed to trade with America, were,

Alicant and Carthagena for Valentia and Murcia,
Corunna for Galicia,
Gijon for the Asturias,
St Andero for Castile,
Barcelona for Catalonia and Arragon,
Cadiz and Seville for Andalusia.

The limitation of the trade to these particular seaports, arose from a view partly to facilitate the collection of duties, and partly to preserve a superintendence over the persons embarking for the western hemisphere. It deserves to be recorded as a memorable proof of narrow policy, that the permission to the Spanish American provinces to carry on a free trade with *each other*, was not granted till 1774. So discouraging to the first active powers of the colonies, was this system of extreme monopoly, that the Spaniards, who are great consumers of cocoa, and who possessed in America the finest soil and climate for its growth in the world, were actually obliged to make importations of it from other countries. The island of Cuba, the most fertile perhaps of any in the American Archipelago, did not, in 1765, employ twenty vessels, but within twelve years after the abrogation of the monopoly, it employed two hundred. Even the city of Cadiz, which clamoured most loudly against the opening of the trade, reaped most important advantages from the change. It continued the emporium of colonial intercourse, and found its proportion advance in the same favourable ratio as the trade of the kingdom at large. Cadiz is to Spanish America what London is to the British settlements; more than half of the colonial trade being conducted respectively in each of these ports.

No country in Europe was less fitted to derive advantage from a large track of colonial possessions than Spain. The indolence of her inhabitants, the bigotry and ignorance of her government, have had the effect of perpetually keeping her bare of capital; and so far from being able to spare funds for transatlantic cultivation, she was destitute of the stock requisite to do justice to her own provinces. Hence one great cause of the miserable progress of her colonies, though possessed of natural advantages that excited the envy of the world. For such a government, and such a people, it was perfectly natural to confine their exertions to the working of mines, and to overlook the incalculable treasures which would have rewarded the labour of the agriculturist. The progress of the Spanish settlements accordingly has been great in population only, the natural and direct consequence of an overflowing stock of provisions. It was, until lately, a very prevalent notion, that Spain and Portugal had suffered, both in population and in capital, by their colonies. Those who contrasted the extensive influence of Philip II. in the affairs of Europe with the insignificant figure made by the subsequent possessors of his throne, did not hesitate to account for the difference by the exhaustion consequent on the transfer of subjects and of capital to the western hemisphere. It is now, however, ascertained, that Spain was never so populous as at present; that in the course of the last century she has nearly doubled her numbers; and that her fall in the scale of political power is to be ascribed, not to retrogradation on her part, but to a more rapid advance on that of her northern neighbours. These considerations are correctly, though we admit very diffusely, illustrated by M. Laborde in his voluminous account of that kingdom. A similar course of reasoning, as far at least as regards the colonies, is followed, (Vol. I. p. 396. et seq.) by Mr Brougham in his *Colonial Policy*.

In regard to population, the Spanish colonies differ both from the United States and the West India Islands. The disproportion of whites is smaller than in the latter, while, on the other hand, their number in no degree approximates to that of the former. The immense field open to agricultural labour would have the effect of giving a general character of steadiness to the inhabitants, were not the lottery of mining perpetually holding forth a temptation to depart from the gradual, and, in the eye of an ardent calculator, tardy progress of agriculture. In their sanguine anticipations, the insecurity inseparable from mining concerns is greatly under-rated, while the progressive, but eventually large returns of agriculture are accounted of little weight in the scale. The fact, however, is, that the advance of agriculture is not only more sure, but frequently more rapid than that of commercial settlements; and the reason is plain, the market of the former exists chiefly among themselves, while that of the latter is dependant on the caprice of foreign nations.

The island of Cuba has, during the present age, made more rapid advances than any other part of Spanish America. The number of its negroes in 1787 exceeded 50,000, and they have been since in a state of progressive increase. There being no restriction on the mode of manufacturing sugar, it is common to clay it before exportation, and as it thus becomes of greater value by twenty per. cent, a proportional saving is made in regard to freight. The sugar is packed in boxes weighing generally 4 cwt. 1 quarter English, and the annual crop is computed (*War in Disguise*, 3d. edition, p. 230) at eighty or ninety thousand hogsheads.

Portuguese colonies.

Portuguese Colonies.—The Portuguese have certainly ranked next to the Spaniards, in the art of mismanaging colonies. They did not, indeed, for a long time, commit the error of establishing an exclusive company for their splendid acquisitions in the East; but they did what was fully as impolitic, they vested the trade in the hands of the executive government. The king granted from time to time the permission of making exports and imports to certain partnerships and individuals, who thus enjoyed temporary monopolies. This hopeful course was, in a great measure, abandoned in the year 1752; but the change, as to the India trade at least, came too late, that branch of commerce being no longer worth following. Brazil becoming progressively more populous, would have afforded a beneficial commerce to Portugal, had the intercourse not been conducted in the true spirit of exclusion and monopoly. Unfortunately about a century ago, at the time when better principles might have been brought into operation, discoveries were made of gold and diamond mines. These discoveries were pernicious to Brazil in two ways; they turned capital from agriculture to the precarious, and, in general, unprofitable labour of mines, while they redoubled the vigilance of government in regard to restraints on the communication with the colony. A late traveller, Mr Mawe, whose report, if deficient in literary attractions, possesses the merit of much clearness and candour as to matters of fact, confirms most explicitly the opinion, that the condition of the inhabitants is much more uncomfortable in the mining than in the agricultural districts. By a singular absurdity, the Portuguese ministry resorted, in the middle of the last century, to the plan of an exclusive company for Brazil, after the rest of Europe began to see the folly of these privileged associations. This took place during the administration of the well-known Marquis de Pombal. A long course of misgovernment has thus retarded the improvement of Brazil, and the chief part of it continues at the present day in a state of nature. The Prince Regent's estate, for example, though nearly equal in size to one of our counties, and highly favoured, both in soil and climate, is not sufficiently cultivated to support two thousand persons. How greatly the mercantile importance of Brazil has been overrated by our traders, has been sufficiently apparent, from the long lists of bankruptcies originating from shipments made to that quarter. Our exporters allowed themselves to imagine that Brazil was already peopled by a nation qualified to use and enabled to pay for immense supplies of British manufacture. Now the true way to appreciate Brazil, is to direct our estimates to its future capabilities, and to postpone our expectations of extended trade, until the lapse of another age has given it a new character. But, considered relatively to the smallness of the mother country, Brazil, even in its present state, becomes an object of importance. It is said (Brougham's *Colonial Policy*, Vol. I. p. 485.) to supply a fourth of the national revenue, and to furnish to the harbours of Portugal as much import trade as they receive from all Europe together. The power, likewise, of admitting or excluding the maritime nations of Europe from the ports of Brazil, tends materially to increase the political influence of Portugal.

British colonies.

British Colonies.—Though our maritime enterprizes against the Spaniards, and our projected settlements in Guiana, were prompted by the hope of golden treasure, the case was very different in regard to North America. A desire to exercise in freedom the profession of their religion, was a powerful motive of emigration with the early colonists; and in the middle of the seventeenth century, our civil wars supplied a new motive for seeking a foreign asylum. As the country became cleared, and as the reports of acquired fortune, always exaggerated at a distance, prevailed among the home connections of the settlers, fresh adventurers were induced to undertake the passage across the Atlantic. Though the English, nationally speaking, are not fond of emigration, the maritime habits of a proportion of the people, and the idea that a boundless field was open to the exertions of enterprise and industry in this unexplored hemisphere, proved the means of contributing successive additions to the number of the colonists. The main source, however, of increasing numbers, was the practicability, from abundance of provisions, of early marriage. All these causes concurred to raise the population, by the middle of the 18th century, to more than two millions, a number which, though not one-fourth of the present stock, was greatly beyond any calculation likely to be suggested in a former age, by the appearance of a wooded, and at first unhealthy region. It deserves also to be remarked, that the religious disposition of the original settlers, and the serious habits impressed on their descendants by the necessity of continued labour in retired situations, have given the Americans, particularly those of the northern and middle states, a character of more devotion than is generally found among European nations.

In the case of our colonies, a progressive advance to prosperity was not retarded by the unfortunate circumstances attendant on those of Spain. There were here no metallic treasures to excite the cupidity of government, and the settlers being poor, enjoyed, in considerable latitude, the benefit of the political maxim, *laissez nous faire*. Though prevented, in a great measure, from trading with any other country than Great Britain, they were limited to no particular harbours, so that the restriction, in the early part of their career particularly, was not productive of material detriment. Another point, and a most essential one, was that of exemption from taxes; the mother country taking on herself the charge of military protection, not indeed from motives of generosity, but from a conviction of the inutility of attempting to collect any considerable revenue from a thinly scattered population. The colonies in consequence have no financial burden but that of their civil government, which, as they had neither king nor nobles, was abundantly moderate. But while it is admitted that the natural advantages of colonial settlements were less counteracted by illiberal regulations of the parent state in our case than in that of other countries, our acts of parliament on this subject will, at the same time, be found to afford a curious exemplification of the effects of the mercantile system. The produce of our North American and West India settlements was divided into two distinct classes—"enumerated" and "non-enumerated" commodities. The former were exportable to the mother country only; the latter might be sent to any part of the world, if shipped in a British vessel. On analyzing the motives of this important distinction, we find, not the benefit of the colonies, but the imagined benefit of the mother country, the prevailing object with our legislature. Corn was a "non-enumerated" commodity; and as it formed the leading article of produce in our northern colonies, the permission of its free exportation might have been ascribed to parental solicitude for the welfare of our American relatives, had it not been accompanied by a law prohibiting its import into *Great Britain*, the market which of all others would have been most desired by our colonists. Here was a notable example of that unfortunate prejudice which still actuates our landed interest, and makes them consider an enhancement of money not as equivalent to an increase of income. A parallel instance was afforded in the case of the cattle of our colonies. The exportation of them, either alive, or in the shape of salt provisions, was permitted to all parts of the world *except the mother country*. Next, as to the "enumerated commodities," our rule was to compel the importation into Great Britain, exclusively, of sugar, coffee, tobacco, cotton, indigo; in short, of whatever could not interfere with the growth of our own soil and climate. We calculated on thus having a supply for all our own wants in the first instance; and, in the next, a profit on all that we should sell to other nations.

So long as our consumption was proportioned to the growth of the colonies, the positive obligation to ship every thing to Britain was not productive of serious injury to our fellow subjects abroad. In the time of Dr Smith, our growth and consumption corresponded sufficiently to each other; a consideration to which, as well as to the very delicate predicament in which we then stood with our American provinces, we are to ascribe the palliating tone in which a writer, otherwise so independent, thinks proper to speak of the course of our policy towards our colonies. Enough has happened in our own day to give evidence of the injurious effect of forcing our West India settlements to throw all their produce into one market. Since the year 1799, the amount of their sugar crops, partly from extended cultivation, but more from the conquest of foreign settlements, have greatly exceeded our means of consumption. The planter has accordingly been repeatedly forced to send home his produce without obtaining any profit whatever. No consideration of sympathy towards these our unfortunate countrymen was sufficient to overcome the inveteracy of long established prejudice. Our ministers were prevented, by apprehension of clamour, from making any relaxation in the provisions of the law; and the landed interest, instigated apparently by selfish individuals, acted a part wholly unsuitable to their general character. On two occasions, in 1808 and 1811, they mustered all their parliamentary strength to prevent the substitution of sugar for corn in the distillery, although examples of the sufferings of the poor from deficiency of provision were fresh in their recollection.

Another class of "enumerated" commodities was composed, not of the produce of a tropical climate, but of articles of northern growth, such as naval stores, ship-timber, iron, copper, &c. Of these, likewise, we compelled the importation into Britain exclusively, in consideration of the inadequacy of our own growth for our consumption, and of the advantage of increasing our mercantile navy, by confining to British ships the carriage of articles which might otherwise be brought to us in the vessels of foreign countries. In one point, however, our colonies enjoyed unlimited freedom—we mean an intercourse with each other. No restraint was imposed on the navigation from North America to the West India islands, or *vice versâ*, so long as the former continued a part of our empire. From the spirit that dictated these various acts of the legislature, it is clear, that while we were always willing to fight for our colonies, and, with our characteristic promptitude in pecuniary contribution, had no objection to bear the chief part of the burden, we never lost sight of the prospect of a beneficial return in the shape of trade. We calculated, and, as we thought, with unerring policy, that the true plan was to keep the trade almost entirely within ourselves. Hence our resolute adherence to the rule of excluding other nations; hence also our obstinate prosecution of the war to bring back the Americans to a state of dependence. We had yet to learn that they might become more profitable to us in a separate and independent situation; a point which shall be forthwith illustrated in the concluding part. See the *General Observations on Colonies*, p. 756.

We shall next present our readers with several Statistical Tables relative to our West India colonies.

I. *Population of the British West India Islands in 1805, taken from Bryan Edwards' History, and from Returns to the House of Commons.*

Islands.	White People.	People of Colour.	Slaves.
Jamaica	28 000	9000	280,000
Barbadoes	15,000	2130	60 000
Antigua	3.000	1300	36.000
St Christopher's . .	1 800	1[illegible]8	26 000
Nevis	1,300	150	8,000
Montserrat	1 000	250	9,500
Tortola, &c.	1 300	220	9,000
Grenada	1,100	800	20 000
Dominica	1,594	2822	22 083
St Vincent's	1,600	450	16 500
Tobago	900	700	14,883
Trinidad	2.261	3275	19 709
Total	58.955	21,967	524,205

In Trinidad the number of coloured people has increased greatly of late years.

II. *Proportion of Sugar to the Land and Labour employed in its Cultivation in our respective Colonies.*

In Jamaica, it is computed that, on an average, one-half hogshead sugar is raised per acre; two-thirds per negro.

Dominica, the same.

Grenada, three-fourths hogsh. per negro and per acre.

Antigua, one-third hogsh. per acre, and one-half per negro.

St Kitt's, one hogsh. per acre; one-half per negro.

St Vincent's, one hogs. and one-fourth per acre and per negro.

Tobago, one hogsh. per acre and per negro.

III. *Imports of Slaves to British West Indies, on a Medium of two Years,* 1802 *and* 1803, *from Official Returns made to Parliament.*

Islands.	Imports.	Exports.	Retained.
Jamaica	7662	2402	5260
Barbadoes	1050	28	1022
Antigua	434	100	334
St Christopher's . . .	971	124	847
Nevis, &c.	238	. . .	238
Tortola	438	259	179
Dominica	550	34	516
Grenada	1097	2	1095
St Vincent's	1540	. . .	1540
Tobago	172	. . .	172
Bahamas	2523	2230	297
Trinidad	4516	33	4483
Demarara and Surinam	7164	. . .	7164
Total slave trade	28.355	5212	23,137

The most remarkable feature in this outline is the extraordinary number of negroes imported into the Dutch colonies. The slaves exported from the Bahamas went partly to Cuba; partly to the United States.

IV. *Sugar Produce of Jamaica compared with the Produce of the rest of the British West Indies, agreeably to Return to the House of Commons, May 6th* 1806.

In Hogsheads of 13 Cwt. of 112 lb. each.			
Years.	Jamaica.	Other Islands.	Total Sugar.
1793	80,300	83,200	163,500
1794	89 800	73,500	163,300
1795	83,200	45,100	128,300
1796	83,400	47,800	131,200
1797	80,030	41,044	121,074
1798	83,350	67,350	150,700
1799	95.000	98,000	193,000
1800	110.500	67,530	177,830
1801	143,200	79,950	223,150
1802	144,100	117,350	261,450
1803	125,000	87.300	212,300
1804	120,000	109,000	239,000
1805	132,000	92,700	224,700

It appears from the above Table, that the average crop of Jamaica considerably exceeds that of all our smaller sugar islands together. This, however, is to be understood of the British settlements only; for were the crops of the Dutch and French colonies added to those of our Windward Islands, the annual average would considerably exceed that of Jamaica.

V. *Rum.*

Years.	Annually exported to the United States of America. Gallons.	To British North America. Gallons.	To Great Britain and Ireland. Gallons.
1793	536,353	613,898	3,756,800
1794	2,265,177	525,720	2,806,623
1795	2,106,883	204,965	1,861,886
1796	3,267,280	307.124	1,993,350
1797	2,197,450	486.706	1,595,008
1798	1,972,985	384,953	3,866,138
1799	3,201,209	664,258	2,404,982
1800	2,761,384	186,449	3,283,392
1801	3,638,021	569,691	3,940,859
1802	3,925,595	584,678	4,166,113
1803	4,198,154	792,474	3,790,868

We regret to add, that one of the unfortunate consequences of our Orders in Council, has been the loss of the market of the United States for our rum, the Americans having resorted to the alternative of making use of their own corn spirit.

VI. *Tonnage and size of Ships in the West India Trade in* 1804.

	Ships.	Tons.	Medium tons each.
London	326	104,312	324
Outports . . .	188	52,009	277
Scotland . . .	84	17,932	242
Ireland	47		

This statement, short as it is, suffices to shew, that although the ships of the outports make, from their number, an appearance nearly equal to those of the metropolis, the larger portion of the trade remains with the latter. The outport ships frequently make more voyages in an equal period; but, on the other hand, their cargoes are, in a considerable part, consigned to London houses, for whom the outport merchants act as factors.

Our next table is a comprehensive one, and affords the means of estimating the importance of the West India colonies, in regard both to revenue and to the amount of capital which is annually circulated through means of their produce.

VII. *Value of Imports from the West Indies, and the Revenue of which they were productive at the Prices of* 1804-5.

	Quantity.	Value.	Duty, Custom, and Excise.			Revenues.
		L.	*L.*	*s.*	*d.*	*L.*
Sugar, home consumpt—cwt. .	1,966,146	7,569,662	1	7	0	2,654,297
Exported	1,386,289	3,950,924				
Rum, home consumpt—gall. .	2,787.253	2,105,433	0	11	2½	1,563,679

Miscellaneous articles		775,108				106,500
Total		17,002,117				4,519,398

VIII. *Value of Exports to British Sugar Colonies in* 1804.

British produce and manufacture	L. 5,124,210
Irish produce and manufacture	371,560
Foreign articles	250,583
Freight on the above computed	1,436,588
Mercantile commission, &c. 2½ per cent. gross	456,180
Insurance at 4 per cent. in gross	300,000
Convoy duty at 2 per cent.	114,920
	L. 8,054,041

It must not, however, be concluded, that the surplus of imports over exports, is a clear revenue derived to proprietors of West India estates resident in Great Britain. Custom-house tables take no account of the very large sums drawn from the mother-country in the shape of bills of exchange, which are paid away by the planters, partly to the Americans for stores, partly to mercantile residents in the colonies, for the various wants of the estates. The fact is, that, so far from affording a clear return, there has been a regular drain of British capital to the West Indies since the year 1799. When the cultivation of a property has once been undertaken, the planter has seldom any other alternative than that of carrying it on at all hazards. In a country so bare of capital as our sugar colonies, a solvent purchaser is not often to be found; and the creditor who has made an advance, must either submit to a heavy loss, or consent to an extension of his loans, with a view to render the land ultimately productive and valuable.

It has been attempted, at different times, to form an estimate of the total value of capital in the British West Indies. Such calculations are necessarily vague; but it is not unimportant to mention, that, from two different estimates, (Sir William Young's common-place book, p. 25.) the result appears about eighty millions sterling. This valuation is to be understood in a very comprehensive sense, as it comprises negroes, lands, buildings, cattle, dwellings, and even shipping. We conclude our tables on the subject of sugar produce with a minute of the importations for several years from the East Indies.

IX. East India sugars were expected, twenty years ago, to form a great article of importation; but it was soon discovered, that, from our settlements at least, they could not be afforded at so low a rate as the West India sugars. Accordingly, the supplies from that quarter have been comparatively insignificant.

	Hhds. of 13 cwt.
In 1801	4700
1802	4200
1803	5300
1804	8000
1805	4100

The insalubrity of our West India colonies, is a topic too serious and too important to be passed over; but we reserve our documents on this head till we come to make some general observations on the nature of colonies.

New South Wales.

New South Wales.—This article would be incomplete were we to omit noticing a colony of a peculiar kind formed in our own day. Though the experiment of transporting convicts has been found highly expensive, (the whole cost, from first to last, exceeding L. 300 a-head,) and though the practice, as a measure of punishment, is not likely to be continued, the settlement in New South Wales is, as a colony, an object of considerable interest. Its growth, in point of population particularly, has of late years been more rapid than was to be expected from the bad habits of the people, and the desert condition of the country on their first arrival. Imagination cannot conceive a tribe less likely to become useful and productive labourers, than the occupants of this settlement. Distance from home had by no means the effect of operating a reformation in their conduct. They had hardly arrived, when they were tempted to display their habits of knavery even on the poor and miserable natives. Some time after, a theatre being erected, the persons who ventured to resort to this amusement, generally found, on their return home, that their neighbours had made free with their property. It became necessary, in consequence, to destroy the theatre; and it was at the same time found indispensible to erect a stone prison, the wooden buildings of that description having been wilfully burned. A vice equally odious, and productive of more general mischief than the propensity to theft, was a rooted habit of intoxication. Whatever was the price of spirits, a price rising frequently to 20s. a bottle, these victims of depravity were found to expend their last pittance in this ruinous gratification. Such excesses were confined, indeed, to the convicts; but the high profit attending the spirit trade, had a bad effect likewise on the free settlers, many of them being tempted away from the pursuits of agriculture by the dazzling prospects of this noxious traffic.

Such was the state of the colony during its first years. In 1795, Governor Hunter entered on office, and was indefatigable in his efforts to reclaim the inhabitants, and improve the settlement. He continued governor during six years, and, at his departure, the number of colonists of all descriptions amounted to 6000. By this time the natives had become reconciled to their European neighbours. It was a matter of some consequence to suspend their acts of hostility, although their incurable indolence afforded no room to hope for their cooperation in useful labour. They seem to belong to the least promising class of barbarous tenants of the woods; and even in a state of peace, they have little scruple in plundering the corn of the settlers. In the midst of their misery, they ridicule the labour and precautions of Europeans; and, after a temporary residence in a civilized quarter, they are found to return with double relish to their original wildness. Their chief weapon is a spear, which they throw with great force, and with unerring aim, to a distance of more than one hundred and fifty feet. Next to the savages, the Irish convicts proved the most troublesome inmates in this new establishment. A detachment of them arrived in 1800, after the unfortunate rebellion, and were eager to disseminate their seditious feelings among the rest of the prisoners. The vigilance of the governor, however, prevented them from gaining ground, so as to disturb the tranquillity of the settlement.

The colony of Botany Bay differs from our other foreign settlements, in the material point of being a government undertaking. While in North America and the West Indies, each settlement has had to make its own way, and to find its chief resources within itself, the government in New South Wales was authorized to draw capital in large sums from the mother country. The consequence has been, a rapid progress in the formation of the colony, accompanied, however, with an extraordinary degree of expence. Part of that expence, indeed, was unavoidable, in consequence of the wretched habits of the colonists; but part, also, has been very unprofitably incurred. New establishments have been formed on distant points; and one of them, that of Norfolk Island, has been abandoned. Under such a system, we must not expect to find a favourable display of the virtues of industry and economy; nor are military or naval men (who have hitherto filled the station of governors) the fittest persons to give a beneficial direction to the labour of the prisoners. There is now, we understand, a disposition to put an end to farming for government account; a symptom which we hail as indicative of considerable amendments. Among grievances of a different nature, we mean the abuses calculated to excite sympathy and regret, one of the most striking is the want of humanity shewn to convicts on the passage out. This is strongly exemplified by the contrast between our ships of war and the contract ships employed to carry out these unfortunate people. The former have been known to perform the passage, long as it is, without almost any loss of lives, while the latter sometimes lose so large a proportion as a third of the number embarked. This is owing, in some degree, to excessive severity of treatment, but much more to a scandalous embezzlement of the provisions. Equal mismanagement has prevailed in regard to the clothing sent out from home. It has been made up, in the first instance, without sufficient regard to the nature of the climate; and, on arrival in the colony, it has been distributed at once, without attending to the necessity of dealing it out by piece-meal to the thoughtless creatures, who are impatient to sell whatever they do not require for present use.

The convicts, on arriving, are in general released from their irons, and ordered by the governor to work on some public undertaking. A proportion of them are successively removed from public work, to be employed in the country under the free settlers. The number of goverment labourers is farther diminished, as well by deaths as by emancipation for good behaviour, and by expiration of the term of servitude. Those who have been brought up to a mechanical profession, generally find it expedient to practise it here. The noted Barrington belonged to the number, unfortunately not large, of penitent sinners. His conduct latterly became exemplary, and he discharged the duty of chief constable with great propriety. To those convicts who persist in a course of depravity, no mode of punishment has greater terrors, than that of removal to a solitary branch of the settlement. The apprehension of separation from old connections, is, on such minds, of much more powerful operation than the prospect of bodily suffering. Repeated examples have occurred, of criminals returning to their iniquitous course, after a second and a third punishment of the latter description; and the case of one Samuels, (Mann's *New South Wales*, p. 12.) seems to imply, that, in certain individuals, a recurrence to guilty practices is unavoidable.

During several years after the first arrival, the colony was occasionally in danger of famine, from obstacles to the receipt of supplies from home. After progress had been made in clearing the neighbouring district, and the cattle brought over had begun to multiply, this apprehension of course disappeared. At present, the price of corn seems nearly the same as in this country, and the price of butcher meat not much higher. The chief enhancement is experienced in whatever requires manual dexterity and the use of implements. Butter, from the scarcity of dairy accommodations, is twice, or rather thrice, its price in this country. Some progress, however, has been made in manufactures, particularly in the tanning of leather. Malt liquor being an article in general demand, and difficult of importation, the colony contains already four extensive breweries. The total population now approaches 12,000, of whom about a third are victualled and clothed at the public expence, while the others find means to earn their own support. The free settlers, who embarked for so unpromising a region, were not likely to belong to a meritorious class of society, and many of them have accordingly proved a burden on government. No branch of trade is carried on with more activity than the sale of female dresses and ornaments. The avidity to purchase these, in this remote quarter, seems not inferior to the passion for dress in spheres of greater splendour; and the shops are already fitted up with a degree of taste beyond our ordinary ideas of Botany Bay.

We shall conclude our remarks on this colony, by a notice of the principal things which remain to be done for its amelioration. The first of these, recommended as it is both by policy and humanity, is the determination of some specific limit to the state of durance in the cases of transportation for life. Whatever may have been the guilt of these persons, an ultimate prospect of relief, at some time or other, should be allowed to visit their imagination. Without such a prospect, they must continue unprofitable servants to the public, as they must be almost wholly hopeless in regard to their future fate. Another point of some consequence, is the introduction of bankrupt laws. There cannot be a more mistaken humanity, than to prevent the concerns of an embarrassed man from being brought to a decisive termination; as it often happens, that he is induced to cling to a hopeless business, and to pass the best years of his life, without benefit either to himself or his creditors. A third improvement in this colony, would consist in the appointment of a civil governor, the questions of internal regulation becoming now too numerous for a military tribunal. A fourth object of attention, should be the nomination of a chief justice, who, whether he take law or equity as the rule of his decisions, should be a man of ascertained ability and experience. The colony supplies few persons fitted to act as justices of the peace; and not many, perhaps, qualified to discharge with impartiality the functions of a juror. Hence the necessity of a judge going out from Britain, and of a form of procedure sufficiently simple and expeditious, to enable him to transact the judicial business of the settlement, as well as to save to the colonists a great part of the ordinary expences of law.

Dutch colonies.

Dutch Colonies.—The settlements of the Dutch in America have not been proportioned to the greatness of their maritime means. After conquering, in the seventeenth century, a great part of Brazil, they found it impracticable to retain it against the will of its Portuguese population. In the north, their colony of Nova Belgia was conquered by us in the reign of Charles II. and became an English province under the name of New York. The cause of so lukewarm a disposition towards America on the part of the Dutch, in this their era of power and vigour, is to be sought in their predilection for their possessions in the East. These possessions embraced the Cape, Java, the spice islands, part of Ceylon, and several maritime stations on the continent of India. The commerce carried on between them and the mother country was very considerable, and passed, in the eyes of most men, for the pillar of the national wealth. In that age, the superiority, in productive power, of inland over foreign industry, was unknown. The notion, that home traffic is an unprofitable transfer from hand to hand, and that national gains are obtained only from abroad, was then still more general than at present. From the imposing magnitude of the India ships, and the long catalogue of Dutch stations and provinces, it was natural to infer, that an extraordinary amount of profit must arise from such a source. The writers of the last age went the length of pronouncing the Dutch possessions in the East much more valuable than the mother country: a notion a good deal similar to that of the French of the present day, who believe Bengal to be the main spring of British revenue. These considerations, partly well partly ill founded, had the practical effect of inducing the Dutch to keep up with great care their eastern acquisitions, while, in the West, they aimed at nothing beyond the small islands of St Eustatia and Curaçoa, along with a continental track in Guiana, which, in recent times, has owed much to British improvement, and has become familiar to us by the names of its subdivisions,—Surinam, Demarara, Essequibo, and Berbice.

As the Spaniards have been accounted the mildest of European taskmasters of negroes, the Dutch have been accused of falling into the opposite extreme. These contrasts, however, are generally exaggerated, and, on analysing the matter, we should probably find that the character attributed to the Spaniard arose from his being too indolent to keep his people at work, while the Dutchman, accustomed to labour himself, made a point that his servants should follow his example. The Dutch West India company was incorporated in 1621, a brilliant æra in the long struggle of the Hollanders for national independence. Spanish America, as well as Brasil, were open to the aggressive warfare of the Dutch, and their new company performed less the part of traders, than of directors of the naval exertions of their countrymen in the West. When political circumstances produced a cessation of the long contest with Spain, the unfitness of a great company for the management of concerns, merely commercial, was felt, and, in 1674, the association was dissolved. A second company was formed, but with no other monopoly than that of the African slave trade; and in 1734 the latter likewise was laid open, on condition of the traders paying certain dues to the company. The Surinam company was a kind of emanation from the larger association; the latter on obtaining, in 1682, certain privileges from the States General, for the supply and management of Surinam, admitted two new parties to the contract, in consideration of their sharing the expence of the charter. These parties were the city of Amsterdam, and the opulent family of Sommelsdyk. The business of the association was managed at Amsterdam by representatives from each of the parties, but all the vigilance and economy of Dutch directors were unable to form a counterpoise to the disadvantages inherent in mercantile coalitions. The stock of the company never rose to par, and fell eventually so low as thirty per cent. These examples of failure, on the part of the Dutch, are the more remarkable, because Holland was, of all countries, best fitted to supply the large advances required for newly settled countries. The interest of money in Holland, so far as 150 years ago, was very low, and did not, on undoubted security, exceed three per cent. while in England it was nearly double. The consequence has been, that while in this country no merchant has advanced capital to a colonist without obtaining a commission in addition to interest on his money, the Dutch capitalists have not hesitated to make loans on the security of West India plantations, for mere interest, in the same way as in London a banker subscribes to a government loan on the security of stock. The extent to which this kind of business was carried, affords a striking proof of the ease with which uncultivated regions might be rendered productive, if the fruits of industry were not wasted in war expences. Thirty years ago the capital due by the colony of Surinam to the mother country, amounted, says M. Malouet, to eight millions sterling. This sum, large as it was, bears a small proportion to the mass of additional debt incurred by the planters, since they came under our dominions seventeen years ago. The high price of sugar in 1797 and 1798, induced our merchants to make very improvident advances for the purchase of negroes, as well as for other purposes; and the subsequent fall of sugar prevented that repayment, which, with the ordinary confidence of West Indians, was anticipated in the course of a few seasons.

French colonies.

French colonies.—The foreign settlements of France have differed from those of Holland, in being more extended in the West than in the East. In the war of 1756, the military talents of Lord Clive, and the decided superiority of our navy, put an end to the question of ascendency between the French and English in the Eastern world. The same war stripped them of Martinique and Guadaloupe, although our solicitude to consolidate our North American possessions led to the restoration of these islands at the peace. But the pride of French colonies was St Domingo—a settlement never wrested from the mother country until the miserable disorders of the late revolution. At first the inhabitants of the French part of St Domingo, and of the adjacent islands, were composed of the free-booters, so well known under the name of *Flibustiers*, or Buccaneers. Two centuries ago, this lawless and intrepid race, an assemblage of pirates and desperadoes from all nations, were the terror of the Spanish Americans. Their situation, which was chiefly in the Bahamas and the quarters we have mentioned, afforded many facilities for adventurous enterprize, and deeds were performed which might supply many a subject for heroic poetry. Part of these atchievements have been rapidly traced by the animated pen of Raynal. In the course of time, the extension of regular government throughout St Domingo, and the rest of the West Indies, led to the incorporation of the descendants of these free booters into the mass of inoffensive citizens. The French colonies, being released, after the failure of the Mississippi scheme, from the restrictions of an exclusive company, advanced in population and prosperity with a success approximating to that of our colonies in North America. St Domingo became the greatest sugar and coffee colony in the West Indies, its population being computed, before the revolutionary disasters, at half a million of negroes, along with a correspondent proportion of whites.

The French colonists, like the English, went abroad only for a season, and steadily cherished the hope of returning with a competency to their native country. This feeling, however patriotic, is productive of an impatience in money making, which not only frequently defeats its object, but interferes very materially with the comfort of the colonist. Even in the long settled island of St Domingo, an island where the proprietors were much oftener resident on their plantations than in the English colonies, the want of domestic comfort was universal. "On n'y voit point d'homme," says Malouet, "assis sur son foyer parlant avec intérêt de sa ville, de sa paroisse, de la maison de ses péres. On n'y voit que des auberges et des voyageurs. Tout correspond à l'idée que j'exprime. Entrez dans leurs maisons, elles ne sont ni commodes, ni ornées; *ils n'en ont pas le tems*; *ce n'est pas la peine*; voila leur language. Est-il question d'un bâtiment, d'une machine, d'une transaction, d'un acte de partage, d'un réglement de compte; rien n'est fini, rien ne porte l'empreinte de la patience et de l'attention." Though disappointments in trade prevent the acquisition of fortunes in the limited period anticipated in their sanguine calculations, bad health, and impatience of an exile from home, are nevertheless productive of incessant removals. "Ici," adds Malouet, "la scène et les acteurs changent en moins de dix années: vous avez sans cesse des hommes différens; sans patrie, sans famille, sans projets, sans moyens déterminés; mais prêts à saisir tous les projets, tous les moyens." This colony, now sunk beyond redemption during the present generation at least, was, in natural fertility, greatly superior to the British settlements. On the sugar estates, the average annual produce of an acre is said to have been nearly one and a half hogshead, a quantity double, as appears from the preceding Table, the average of our colonies. St Domingo is said to abound in the fine brick mould, which in Jamaica is found only in particular districts. Accordingly in a period of ten years preceding the horrors of the revolution, the negro population, as well as the amount of produce, are believed to have nearly doubled. Martinique and Guadaloupe, though greatly behind St Domingo, have long been important colonies, their joint exports having amounted, many years ago, to a million sterling. The annual importation of slaves into the French colonies, before the revolution, was between 20 and 30,000.

The amount of produce exported from them, was	L. Sterling 8,000,000
The shipping employed	Tons 160,000
Number of seamen	above 30,000

The British West India trade was in value about two-thirds of the French; while the number of our seamen employed in it, in consequence of their superior dexterity, was less than half. In fact, the West India trade occupied half the mercantile navy of France, while, in our case, its proportion to the whole was not more than a ninth. The total of our mercantile tonnage, previous to the French revolution, was three times that of France; the number of our seamen was double. It deserves to be remarked, that, in the West India trade, the average size of British shipping is nearly 300 tons, while of French West Indiamen, so lately as the years 1791 and 1792, the average (Brougham, vol. i. p. 177.) was below 100 tons.]

Danish and Swedish colonies.

Danish and Swedish Colonies.—The northern powers were, at the time of the great discoveries of the sixteenth century, too insignificant to obtain any considerable share of these distant acquisitions. Their trade, as Sir William Temple says, was "war," and war conducted on land and in their own neighbourhood. About two centuries ago, Denmark acquired some small settlements on the coast of Coromandel; and agreeably to the current practice, put them under the management of an exclusive company. This company shared the ordinary fate of these associations, and became insolvent. It was succeeded, in the course of years, by a second, a third, and even by a fourth company, all of whom arrived at the same end; the demise of the last, however, being procrastinated, as in the case of our own East India Company, by the union of territorial sovereignty with the possession of the exclusive trade. At last, in 1777, the crown purchased the rights of the company, and opened, under certain limitations, the India trade to individuals at large. In 1792, these limitations were farther relaxed, and all persons, whether Danes or foreigners, were permitted to trade with India, on condition of bringing their cargoes to Copenhagen. The long war which followed, and involved all the south of Europe, threw a great deal of India trade into the hands of the Danes; and their flag was used as a convenient medium by private traders in our own country. It has been for a century past, the policy both of Denmark and Sweden to avoid maritime war, and to profit by the hostilities of other countries. Nothing but the pressure of necessity would have made the Danes depart from this course in 1807.

The West India colonies of Denmark consist of Santa Cruz, and of two insignificant islands. This trade was formerly vested in the hands of a company who failed; and for a long time this trade likewise has been open to all inhabitants of Denmark, with hardly any other restriction than that of bringing their produce to the capital, or to a port which is privileged to erect a sugar refinery.

Sweden possesses no colony except the small island of St Bartholomew, which was obtained thirty years ago from France. The trade with this little spot is also under specific limitations, Stockholm and Gottenburg being the two privileged harbours, and an association bearing the name of a West India Company possessing the direction of the intercourse. The returns, however, do not probably amount to £50,000 a-year. The Swedes have likewise an East India Company, whose dealings are very limited, and who are in the peculiar, but probably not unfortunate situation of possessing no Indian territory.

General Observations.

Motives for emigration.

Motives for Emigration.—It is common to make a distinction between ancient and modern colonies, by ascribing the origin of the former to the want of subsistence, and that of the latter to commercial projects. The distinction, however, holds less generally than many are inclined to suppose. The want, or rather the imagined want, of subsistence, had a powerful operation in sending abroad many of the English emigrants to North America. Mr Brougham has caught this idea, and is at great pains (vol. i. p. 94.) to shew, that, in the progress of society, certain classes may be exposed to a very sensible diminution of their accustomed enjoyments, and consequently acquire a disposition to emigrate. While we have great pleasure in bearing testimony to the ability of his illustrations in this and several other topics, in his *Colonial Policy*, we cannot help thinking, from the length of his observations, that he has sought too far for the motives which lead to the exchange of an old for a newly settled country. In our opinion, the comparison which an ardent mind is prepared to make between the unbounded prospect offered by the one, and the well-ascertained toil and trouble attendant on a continued residence in the other, is amply sufficient to account for such emigrations. As to the facility of obtaining subsistence, we are inclined to think that most long settled countries are on a par, for the plain reason, that an increase of population is invariably found to attend an increase of provisions. Ireland contributes annually a considerable number of colonists to the American states; and the emigrants, be it remarked, are chiefly from the Protestant part of the population. Now, on the score of subsistence, the Irish Protestants are less uncomfortably situated than their Catholic neighbours who do not emigrate; a fact which shews that the influence of necessity, in this case, is a relative, not an absolute feeling. Moreover, a passage to America costs at present, and, we believe, always did cost, a sum which, small as it may be, would afford to the emigrant the means of subsisting at home for a season. Our opinion, therefore, is, that the want, not of a mere subsistence, but of a comfortable livelihood, has been the chief motive for emigration in modern as well as in ancient times; and that this want was not, in general, the result of any sudden or particular change of circumstances, so much as of the predilection with which a man, aware of the necessity of prolonged labour at home, is apt to contemplate his prospects in a new country. Adverting to the case of Scotland, we admit the Highland emigrations to have been, in general, the result of a direct cause,—the loss of employment to the inhabitants, by the extensive introduction of sheep-farming. On the other hand, the annual drain of our young countrymen from the Lowlands to the West Indies, affords a striking example of the relative nature of the consideration mentioned above. They go abroad in quest, not of a mere support, but, as they imagine, of a more comfortable one than they can find at home. A farther argument in favour of our view of the cause of emigration, is to be found in the agricultural situation of Great Britain. Until the middle of last century, or rather until the year 1770, we were in the habit of making annual exportations of corn; a sufficient reason for not going out of the country in quest of a bare subsistence. Ireland at the present day is a corn-exporting country; and were the husbandry of Lothian, Berwickshire, or Northumberland generally introduced into the more favourable soil and climate of the west and south of England, a material alteration would ensue. Great Britain would cease to be dependant on foreign countries for corn, and might be enabled to maintain even an additional population from her own resources.

Causes of colonial prosperity.

Causes of Colonial Prosperity.—Various reasons concur to accelerate the progress of a colony in the career of wealth and consequence. The country chosen for a colony has generally the advantage of a good soil and climate. The colonists, emigrating from a civilized quarter, bring along with them the habits both of industry and of subordination. They bring also a small capital, not perhaps in the shape of money, but in that of tools, or other productive stock; and they are little actuated by that ostentation and disposition to expence, which, in our part of the world, interferes so materially with the augmentation of property. Utility is the great object in a new settlement, and the habits of consumption do not greatly exceed the limits of necessity. Their towns are few, and, for many years, of small size, so that the majority lead a country life: a situation of all others the most conducive to habits of economy. The local government is generally guided by a correspondent train of feeling. It meddles little with foreign affairs, seeks no quarrels, and confines its expenditure within very narrow limits; the consequence of which is, that the taxes are very light, and the citizen is left in possession of almost all the fruits of his labour. The augmentation of property would be still quicker, were capital abundant among them; but men of capital do not emigrate, and in new colonies, consequently, the rate of interest is high. Of all the advantages, however, of a new colony, the most important is the abundance of subsistence. The woods which afforded a scanty support to a few families of savage hunters, are converted, by the axe and the plough of the farmer, into luxuriant corn fields. In such a country, a numerous family of young persons, instead of being a burden on their parents, become a source of additional income. Uncleared land is to be bought for a trifle, so that the means of extending cultivation are within the reach of all persons above the lowest rank. One of the chief consequences of this state of things, is discovered in a high rate of wages. Where people multiply so fast, the great want is the want of labourers to provide for their accommodation. The domestic and the mechanic are much more independent of their masters, than in a country where a recourse to agricultural habits is impracticable. These circumstances, if not calculated to make them respectful in behaviour to their superiors, have, politically speaking, the good effect of affording strong inducements to industry. The journeyman in a town, like the labourer in the country, is enabled soon to engage in business on his own account, and to pay his assistants the same liberal rate of wages which he formerly received. In such a community, the chief expence of a family consists in the price of the manufactured articles, which it is necessary to import from the mother country, or from some long settled quarter; and which, in compliance with the vulgar notion of loss by consumption, are generally saddled with heavy duties. Another serious article of expence, consists in servants' wages, which, like all other wages, are, in such a situation, very high.

In the existence of these circumstances, varied, as they necessarily are, by difference of situation, we shall find an explanation of the rapid growth of almost all colonies. Were our materials sufficient, we might be enabled to trace their operation in the ancient settlements of Asia Minor, Italy, and Sicily, as clearly as in the well authenticated history of New England, or of the territory adjacent to the Cape of Good Hope. It was in consequence of such causes, that Tyre rose superior to Sidon, and Carthage, in her turn, to Tyre. The population of the thirteen United States of America bids fair, before the expiration of the present century, to surpass that of the greatest nations in Europe. In point of literature and works of taste, our American brethren, it must be confessed, are hitherto much behind the brilliant example of the Grecian colonists. The spirit of trade seems, in the United States, almost wholly to absorb that time and attention which, in other countries, is shared with more refined pursuits.

Insalubrity of tropical settlements.

Insalubrity of Tropical Settlements.—Powerful as are the above-mentioned causes of colonial prosperity, their operation will be found more applicable to the state than to the individual. The facility afforded by them, is not that of making a fortune, but of rearing a family. In speaking accordingly of colonies, such as the West Indies, where, from unhealthiness of climate, and deficiency of the comforts of life, the settlers do not contemplate a permanent abode, we must make very considerable deductions from the operation of the favourable circumstances of colonies. The advantage of bringing up a family at a cheap rate, becomes, in a manner, lost in such a situation; the settlers either not marrying at all, or finding it expedient to have their children educated in Europe. Here lies the great difference between our sugar colonies, and the more congenial climate of the northern part of America. Were our young countrymen, in particular those north of the Tweed, apprized of the real nature of a West India life, they would discover much less eagerness to try their chance in so hazardous a career. They take up a vague notion of the wealth of the West Indies, from the example, perhaps, of a few individuals in their neighbourhood, who, having realised a competency, get credit, throughout an uninformed circle, for being men of fortune. The young adventurer is too little acquainted with the world, to make the requisite deduction from the sums, of which the vanity of these envied persons, or of their friends, represents them to be possessed. He is likewise too little aware of the danger of the climate, to calculate how many have fallen victims to it, without in any degree attaining the object of their emigration. The fact is, that during the last fourteen years, the acquisition of property in the West Indies has been much more difficult than at home. If, for the sake of taking the matter on its fair side, we consider the bad times at an end, and regard the colonies as restored to their ordinary course, we shall still find very serious deductions from the supposed rapidity of money-making. The expence of living—the high interest on borrowed funds—the endless procrastination of payments—the accumulation of law expences—the frequent occurrence of losses by the death of debtors, who, like most men in that country, have no property but their personal exertion, are all obstacles to the success of even the prudent and industrious settler. When to this unpleasant list we add the decay of constitution by the climate, there seems no doubt of the balance being in favour of a life passed, however laboriously, in the mother country. Admitting the acquisition of property in the West Indies in a given number of years to be quicker, it is not greater (nor by any means equal) when a suitable deduction is made for the effect of climate in abridging the duration of life. A large proportion of the settlers are cut off in the outset of their career, and the survivors are, in general, found by middle age to have advanced much nearer to a state of infirmity, than if they had remained inhabitants of their native clime. Sir William Young, among other useful documents on the West Indies, has given the public tables of the mortality among the British troops in the West Indies. He divides the year, very properly, into two parts; the dry and healthy period from December to June, and the rainy season from July to November. In the latter interval, the mortality (see his *West India Common Place Book*, p. 220.) is more than double the former; and, putting the whole year together, the proportion of deaths among our troops, even without taking the field, or undergoing particular fatigue, is eleven in the hundred. This computation proceeds on the supposition of newcomers arriving out at the most favourable time, viz. the beginning of the dry season. It is greatly below the average loss of the British troops in these colonies, on a computation of seven years, of which Sir William presents the following melancholy picture.

Table shewing the mortality of British troops in the West Indies (exclusive of those who fell in action) during seven years, from 1796 *to* 1802 *inclusive, compiled from regimental returns by John Sayer, Esq. army commissary.*

	European soldiers.			Negro soldiers.			Officers

On considering the inexperience of young emigrants to the West Indies, we apprehend, that the proportion of casualties among them does not fall greatly short of the conclusion suggested by this distressing catalogue; and that, on a comprehensive calculation, the average chance of life among these imprudent adventurers does not exceed *six or seven years*.

In comparing the East and West Indies on the score of health, we find a considerable difference in the fate of Europeans in these respective quarters. Though the degree of heat is, generally speaking, greater, and of course more unfavourable to a northern constitution in India, the cases of mortality are of less frequent occurrence. The explanation of this difference, is to be sought in the superior accommodation, and means of prolonging life in a cultivated and well inhabited country. Accordingly, while in the West Indies, the lot of our countrymen is either a sudden decease, or the preservation of considerable vigour, the European residents in India exhibit many examples of life protracted in spite of an enfeebled constitution. The habit of exaggerating the amount of property acquired at a distance, prevails, above all countries, in regard to India. A French writer, M. de Montgaillard, has lately gone the length of declaring, that "Bengal, and not England, is the main spring of British wealth; Calcutta, not London, the emporium of our commerce." Those among our countrymen who have tried India, and have had practical experience of the absurdity of these exaggerations, are accustomed to consider the last age as much more favourable to fortune making in India than the present one. We, on the other hand, are inclined to suspect that there has been all along a general misapprehension in regard to the magnitude of India fortunes; but, without dwelling on this matter, we shall briefly advert to two points, both of a nature to modify considerably the magnificent conceptions of the treasures of the East. These are, the long period almost uniformly required by our countrymen in that quarter to realize a competency; and the necessity apparently incumbent on the majority of them to remain unmarried until they are past middle age—a time when they must forego the hope of living to see their posterity settled in the world. The truth is, that in nine cases out of ten, the money made in India is made by saving; it is the result of the combined operation of time, and of a calculating economy. Of late years, however, it has experienced a considerable check, its main source, the high interest of money, having undergone a material reduction.

We have dwelt the longer on the mistaken ideas entertained in regard to our East and West India settlements, because an accurate knowledge of these vaunted regions would tend greatly to reconcile our countrymen to habits of steady industry at home. Those, however, who are bent, at all hazards, on trying their fortune abroad, would do well to bear in mind the difference between a southern climate and that of Canada, Nova Scotia, or the northern part of the United States, where, in favourable situations, and with prudent management, the chance of health is nearly as good as at home.

Nature of colonial trade.

Nature of Colonial Trade.—The colonial policy of England, and of other countries, has proceeded on the assumption that the trade with our foreign settlements was essentially different from the home trade. Our legislature has cared very little whether the colonists had a profit or not, provided we obtained a profit ourselves; and wherever the respective interests appeared to clash, there was very little discussion about which should give way. Now the fact is, that the colonial trade is in principle the same as a branch of home trade, with the single exception of distance of situation. In dealing with the continent of Europe, one capital is British, the other foreign; the profit is divided between us and the subjects of another government. But in the case of our colonies, both ends are British, and the total profit centers among ourselves. The difference between the home and colonial trade consists not, as many imagine, in a distinction of interests, but in a comparative slowness of returns. This is a matter of great consequence, both in a general and individual light, and as it is very little understood by persons out of trade, it may be useful to explain it at some length. In newly settled countries there is an extent of employment, almost indefinite, for capital and the rate of interest is consequently high. The inhabitants, having very few funds of their own, carry on their concerns in a great measure on a capital borrowed from their connections in Europe. They are proverbially slow in their repayments; and it has likewise been the policy of most colonial legislatures, with a view to forward improvement, to throw impediments in the way of the recal of money advanced on loan to settlers. The law is favourable to the creditor, as far as regards the provision of security, and the payment of the full rate of interest, but it gives him little aid in regard to the resumption of the principal. The consideration for all this delay and uncertainty in colonial business, consists in allowing a higher rate of mercantile commission than in the home trade. Notwithstanding this counterpoise, the unfortunate course of things, during the last fourteen years, has created a general aversion from colonial business. Instead, however, of pronouncing it a line absolutely disadvantageous, and home trade absolutely the reverse, it is more correct to regard the former fitted for a merchant of large, and the latter for one of small capital. Failures in the colonial, as in other branches of commerce, originate almost always from people going beyond their depth. Whoever advances money in the colonial trade, must be prepared to consider that portion of his capital as removed for a length of time from his controul, a course which no prudent man will allow himself to pursue in regard to the whole of his property. When a correspondent is found to disappoint expectation, it would be idle, in the present state of our colonial law, to seek a recovery in a court of justice. The proper plan is to apply to another mercantile house, more affluent or more adventurous, and to make it their interest, by a sacrifice, either of a part of the money, or, more properly, of time in regard to repayment, to take over the concern, with its profits and its responsibility, giving security for the ultimate reimbursement of the original lender. Merchants trading to colonies so recently settled as Trinidad, Tobago, Demarara, or Surinam, find infinite difficulty in avoiding a progressive and serious augmentation of advance. In quarters which approach to a more complete state of cultivation, as Barbadoes, Antigua, St Kitt's, the wants of the borrower being more easily ascertained, there is less hazard of additional demands. Jamaica being in some parts highly cultivated, while in others it has extensive tracks of land in a state of nature, may be said to partake of either situations; though the vexations characteristic of a new colony must be allowed to predominate. From all these considerations it follows, that our colonial trade, without being necessarily disadvantageous, or, as a long course of distress has made it be termed by many, ruinous, is a branch of business fit only for particular persons; we mean, persons both of large property and of long experience in the line. It centers, in a great measure, in London, and is much more suitable to the habits and circumstances of merchants in the metropolis, than to those of the outports. The latter, limited as they are in point of capital, would consult their interest much more by confining themselves to the capacity of agents for the former, than by attempting a direct connection with the planters.

Negro labour.

Negro Labour.—That impatience to change the scene of residence, with which M. Malouet so strongly charges the French planters, happens, we must confess, to be fully as applicable to our own. The continuance of the practice of performing labour on sugar estates by means of slaves, may be traced, though somewhat indirectly indeed, to the influence of this feeling. The eagerness of planters to buy negroes at a price much beyond what it would have cost to rear them, was an evident consequence of the disposition described by Malouet. A similar cause seems hitherto to have prevented any deliberate examination of the expediency of providing for the gradual emancipation of the negroes. It has been much disputed among political economists, whether there is in reality any saving by employing slaves. M. Say, one of the most successful commentators on the work of Dr Smith, ventures, in this respect, to dissent from our countrymen, and enters (*Traité d'Economie Politique*, vol. i. p. 215.) into a long calculation of the expence of slave labour. The result is an estimate of L. 20 or or L. 25 sterling as the annual cost of a negro's support, a sum which he contends (p. 218—225) is greatly below the amount of their annual earnings. On the other hand, Dr Smith, Sir James Stewart, and M. Turgot, maintain, that slave labour is more expensive than free labour, because a man in that situation, having no interest in his work or in his savings, toils as little and consumes as much as he finds possible, while the same reason operates to prevent him from acquiring that practical dexterity which seldom fails to reward the persevering attention of the free labourer. At the time when M. Say wrote, (1803), the abolition of the slave trade had not taken place, and the imagination of that valuable writer was impressed with the most gloomy conception of the condition of the West India negroes. The circumstances attending their passage from Africa, appeared to him full of horror. "*C'est* (p. 225.) *le chemin de l'averne qui conduit aux enfers.*" Apprehensive that many ages must elapse before the planters can be prevailed on to change their plan of labour, he proceeds to enquire whether it is not practicable to obtain sugar from other quarters. He cites the well-known M. Poivre as an authority for the low price of sugar in Cochinchina, and maintains, that Europe might derive sufficient supplies from that quarter without participating in the crime of oppressing the degraded natives of Africa. When we consider the much greater length of an India voyage, and the disappointment experienced in the case of the Bengal sugar, so much vaunted twenty years ago, we must dissent from M. Say, and continue to expect our chief supplies from the western hemisphere. Nor are we without hopes of obtaining them without much violation of the duties of humanity. Already very considerable improvements have taken place in the care of negro women and their offspring in their years of infancy. To increase the number of negroes on our plantations, by mild and attentive treatment, is now perfectly understood to be better policy than to overwork them for the sake of making a few additional hogsheads of sugar. Without laying stress, therefore, on the influence of humanity, we may safely trust to the policy of the planters for a disposition to treat their slaves in the way that benevolence would dictate; although, it must be confessed, that they and their white servants have much to learn before they can be accounted capable of doing justice to the health of their humble dependants.

Disadvantages of colonies to the mother country.

Disadvantages of Colonies to the Mother Country.—In bringing our remarks to a conclusion, we shall venture to say a few words on a topic on which mercantile prejudice runs as strongly against us as the feeling of the planters against the economists in the case of slave labour. By way of illustrating our views, we shall have recourse to the sanction of past events. When our North American colonies succeeded, in 1783, in finally obtaining their independence, there was a general belief that the brightest season of our commerce was past. No person ventured to think that our colonial trade would be as profitable as before; and to have said that it was about to become more profitable, would have been accounted a singular example of delusion. The fact, however, was, that the colonies continued to make their purchases of manufactured goods from us in the same way as before, and that their new situation gave them additional means for the augmentation of these purchases. Before the æra of their independence, an export to them of British goods to the amount of three millions, was accounted a most favourable year of trade; but of late, eleven and twelve millions were, in general, exported; and when harmony is restored, we may anticipate a steady export of fifteen millions or more. In analyzing the causes of this auspicious augmentation, we find them of two kinds—increase of capital, and increase of people. Both would have been in a course of advancement had the colonies remained subject to us and our regulations, but the ratio of progress has been much more rapid in their independent state. The way to quicken the increase of capital is to leave its possessor at liberty to buy and sell wherever he thinks proper. In the case of the Americans, the principal change that took place was the purchase in Holland and other countries of a proportion of commodities, chiefly raw produce, which we formerly obliged them to take from us at a higher price. If we reckon the amount of these purchases at L. 1,000,000 a year, and the annual saving to the Americans at L. 200,000, we shall soon find the benefit of the saving in an increased demand for our manufactures. The L. 200,000 saved, formed an annual addition to the American capital, and increased, in a correspondent proportion, their general power of purchase. While one fourth part of it was employed in extending their continental trade, it is no exaggeration to compute that the remaining three-fourths were remitted to this country. From official returns some years ago, it appeared that the United States purchased only to the value of three millions a year from the continent, while from us they took the triple, or rather the quadruple sum mentioned above. (Baring *on the Orders in Council.*) It is evident, therefore, that of every additional guinea made by America, the half, or more properly two-thirds, were vested in British purchases. Need we add more to prove that it is our interest to let them increase their capital in their own way? If we forego a small profit on articles of continental merchandize, we have soon an opportunity of reaping this profit threefold in the extended purchase of our own goods consequent on this saving to the Americans. It is clearly better for us to sell them twelve millions in value of British manufactures, than six millions of the latter, and two millions of continental goods. Now this is no unfair statement of the difference produced by the independent situation of the United States. Had they remained till now part of our empire, they would have been involved in the war of 1793; and even in peace, they would have been without all the saving and consequent augmentation of capital which has ensued from their purchasing continental produce at the first hand.

The course of our reasoning will be rendered clearer by attending to the material point, that in the case of foreign merchandize re-sold to the Americans, the loss to them was much greater than the profit to us. Of the sum of L. 200,000 already mentioned as the computed amount of enhancement, the chief part went in freight, insurance, warehouse rent, and shipping charges, on all of which the clear profit is much smaller than persons out of trade are apt to imagine. The advantage to our merchants on such transactions will not be underrated by estimating the gain of all the parties employed at one-fifth of the L. 200,000. Next as to revenue: Those who calculate on public emolument from the carrying trade, appear to forget that our duties are almost always drawn back on re-exportation. Is it not better, therefore, that a people eager to make an annual extension of the purchase of our manufactures, should increase their disposable capital by L. 200,000 a year, than that we, for the sake of L. 40,000, should cause them a loss to that amount? It may, however, be urged, that the additional employment in the importation and re-shipment of the continental merchandize was productive of considerable advantage to this country. Now, in reply, we have to ask, whether in time of peace any considerable number of our countrymen ever are at a loss for employment? Even in war, the want of work has been very little felt until the Orders in Council, an act of our own, caused a kind of revolution throughout the commercial world. The truth is, that the wants of mankind are such as to supply, necessarily and permanently, an effectual demand for the labour of the industrious; so that we may allow the consumers of merchandize to provide themselves, on all occasions, in the shortest and cheapest way, without disquieting ourselves with an apprehended deficiency of employment. If we apply this course of reasoning, and the practical lesson given us by the example of America, we shall soon see that most governments have overrated the advantage of retaining settlements in the tributary shape of colonies. The value of colonial trade, when free and unrestricted, is, like the value of other branches of trade, of the highest consequence; but the amount of this value becomes materially lessened by the imposition of restraints. While, on the one hand, by favouring certain colonial articles to the exclusion of those of foreign countries, we commit the error so strongly deprecated by Dr Smith, of driving into the colonial trade an undue proportion of home capital; on the other hand, by compulsory limitations in regard to the sale of colonial produce, we cramp most seriously the growth of colonial capital. As matters stand, such sales can take place only through our medium; and had Mr Brougham composed his book with a knowledge of the eventful history of the last ten years, he would not have considered the monopoly in so harmless a light. If farther arguments are wanted to produce the conviction, that our colonies would be more profitable to us in a free than in a restricted shape, we need merely refer our readers to the instructive tract written on this subject by Mr Bentham, at the outset of the French revolution. Nor will it be unprofitable to make a practical contrast between the annual burden attendant on the defence and government of the West Indies, Canada, or Nova Scotia, and our complete exemption from expence in the case of the United States, from whom our mercantile gains are so much greater. See Humboldt's *Travels in Mexico*, Brougham's *Colonial Policy*, Smith's *Wealth of Nations*, Talleyrand on *Colonies*, Say's *Economie Politique*, Robertson's *History of America*, Bryan Edwards' *History of the West Indies*, Sir William Young's *West India Common-Place Book*, and Mann's *New South Wales*. COLOURS, in optics. See ACHROMATIC TELESCOPES, DISPERSION, and OPTICS.

COLOURS, in painting. See PAINTING.

COLOURS, in dyeing. See DYEING.

COLOUR, (*difference of, in the human species.*) Of all the external varieties in the human species, none are so remarkable as that diversity of colour which distinguishes the inhabitants of different regions of the globe. We see it in all its gradations, from the purest white, to the deepest ebony; and the question is, to ascertain the cause of these variations. Two hypotheses have been maintained on this subject; the one is, that all the varieties of colour may be accounted for from the effects of climate; the other is, that there have been, from the beginning, different species of the human race, possessing different colours, as their peculiar characteristics.

The first opinion is the most ancient, and we think it has been demonstrated to be the most philosophical. The ancients, who were scarcely acquainted with any black nation, except the Nubians, regarded them as the terminating shade of the tawny colour, heightened into blackness, by perpetual exposure to the rays of the sun. As far as their knowledge then went, every thing tended to confirm this opinion. They observed the shade of colour gradually to deepen as they approached the equator; whilst those nations which were farthest removed from the torrid zone, were uniformly found to have the fairest complexions: they could not therefore desire a more complete induction of facts to authorise their conclusion, that the different shades of colour were to be ascribed to the effects of climate.

Modern discoveries have greatly enlarged our knowledge, and furnished us with many facts totally unknown to the ancients. There are now found many exceptions to the rule which they adopted, and nations of very different complexions, are found under the same parallel of latitude. This discovery first gave rise to the hypothesis, that different regions of the globe have been peopled with different races of men. But if we take the thermometer for our guide, and estimate by the degree of heat, rather than the degree of latitude, we shall have a rule which approaches nearer to the truth, though subject to modifications which we shall afterwards specify.

It is impossible to estimate the degree of heat in any country, merely by measuring its distance from the equator: its climate is affected by its elevation above the sea, by the height of its mountains, by the extent of continent, or by the nature of its surface. All these circumstances operate with peculiar force on the continent of America, which is found to differ as much from the old world in its surface, and in the temperature of its climate, as its natives differ in appearance from other inhabitants of the globe. There are no blacks found in America, though the torrid zone stretches across its continent. But this is exactly what we might expect, on the supposition that the colour is affected principally by heat. The immense extent of ocean by which its shores are bounded, its lofty mountains, running almost continuously from one extremity of the continent to the other, with their tops covered with perpetual snow, cool the scorching breezes of the torrid zone, and convert it into a temperate clime. Were we then to find negroes in the torrid zone in America, as we find them in Africa, it would be the surest proof that they were a different race from the rest of mankind, as it would be evident that their colour could not be ascribed to the effects of heat. The plain of Mexico, according to Humboldt, is about eight thousand feet above the level of the sea, and this circumstance, though it lies within the torrid zone, must necessarily ensure a temperate climate; the inhabitants, of course, are found to be only of a tawny complexion. Similar causes operate throughout the whole extent of America, producing an uniformity of climate unknown in the ancient world, and consequently a much greater uniformity in the appearance of its inhabitants.

To this reasoning, however, it has been objected, that the difference of colour cannot be ascribed to heat, since tribes have been found within the torrid zone, in Africa, separated from each other only by a river, yet differing widely in appearance and complexion. Thus it is said, that on one side of the river Senegal, the inhabitants are perfectly black, on the other only tawny. If this be the fact, and we are not concerned to dispute it, we must seek for some modification of the principle which we have laid down, viz. that the difference of colour is to be ascribed to the different degrees of heat; and it is easy to account for this apparent anomaly without relinquishing the principle which we have assumed. It is evident, that the form and colour of the human body are much affected by the degree of refinement to which a nation has attained, by the food on which it subsists, or by the occupations in which it is most usually engaged. We observe a wide difference of appearance, in the different ranks of European society, varying, in general, according to the station, or employment of different individuals. May we not expect to see the same difference among rude tribes, placed in the same circumstances as to temperature, but differing widely in their general habits and employments? If cleanliness should ever become an object with any tribe in the torrid zone, or if they should ever alter their ideas so completely, as to esteem *blanching* of the skin a beauty, in that case there can be little doubt that even the Ethiopian might in some degree change the ebon gloss of his complexion. But though we cannot expect this change of complexion to be effected by any voluntary effort on the part of people, who esteem blackness beautiful, and who unquestionably find it convenient; yet it may be produced by circumstances over which they have no controul, or by habits which they may be unwilling to relinquish. There can be no doubt that their colour must be considerably affected by the nature and quality of the food on which they subsist. We see a visible difference in the flesh of the same animals, according to the nature of their food, and we must naturally suppose the same effects to be produced on the human body, by the same circumstances. A tribe which lives chiefly on fruit, or vegetable productions, may be expected, *cæteris paribus*, to differ in complexion from those who live on fish, or animal food; and they who live on clean and wholesome nourishment, from those who feed on coarse and filthy fare.

From these causes it is easy to see, how conterminous tribes may differ considerably in their external appearance, since every thing that influences their habits and manner of living must, in some measure, affect their appearance and complexion.

But besides these permanent causes of distinction, there is another which must not be lost sight of; that is, the recent settlement of various tribes within the limits of the torrid zone. It is a fact, ascertained beyond the possibility of a doubt, that a tribe which has emigrated from a temperate to a hot climate, will be many ages in acquiring that shade of colour which distinguishes the indigenous inhabitants. Were we, therefore, to find two tribes possessing the same habits, and enjoying the same temperature as to climate, yet differing considerably as to complexion, it would be absurd to resort to the unphilosophical expedient of supposing a difference of species, when the circumstance might be easily explained from the recency or antiquity of their emigration. The world is not yet old enough to ascertain the fact, how long it will take to pass from white to the deepest black. As far as our experience extends, however, we see every generation descended from white parents in the torrid zone, acquiring a deeper tinge, and gradually approaching that complexion which distinguishes the perfect negro. We are told that the Portuguese settled at Mitomba, a river in Sierra Leone, have, by their marriages with the natives, and by the operation of the climate, degenerated into perfect negroes, with woolly hair, thick lips, &c. and retaining scarcely a trace of their original, except a smattering of the Portuguese language.

We have as satisfactory evidence, that a similar change is produced when negroes are transplanted to a temperate climate. Every succeeding generation is fairer than that which preceded it, though we are not as yet able to ascertain what length of time is necessary to wash out the constitutional stain from their skin. We have, however, the most undoubted authority for the fact. It is expressly affirmed by the Abbé Raynal, with respect to the descendants of negro parents in North America; and more particularly by Dr Smith, of New Jersey, who has examined this subject with great accuracy of observation, and who informs us, that the negroes, in the United States, though intermarrying with each other, are gradually losing the curled hair and black complexion of their African progenitors.

Thus then, great heat, and the exposure of many successive generations to its influence, are necessary to the production of that colour which distinguishes the negro; and the same length of time, accompanied with an inversion of circumstances, would be requisite to bring him back to his original hue. The Jews afford the most remarkable illustration of these observations: though scattered over the face of the earth, they have in general remained a distinct and separate race, with not a drop of blood in their veins but what has flowed in a direct course from Abraham: yet how various is their complexion? They are found fair in Britain, brown in Spain and Portugal, copper-coloured in Arabia and Egypt, and almost wholly black in Abyssinia, and at Cochin in India.

With regard to the Jews at Cochin, Dr Buchanan, in his *Christian Researches*, furnishes some particulars which show, in a very remarkable degree, the effect both of climate and of long residence. There are two descriptions of Jews at Cochin, the one he denominates black, and the other white Jews, and concludes, evidently without any theory in his head respecting the sameness, or diversity of the human species, that the former owe their dark complexion to their long residence in the country, whilst the latter have not resided long enough to complete the dye. His words are, "It is only necessary to look at the countenance of the black Jews, to be satisfied, that their ancestors must have arrived in India, many ages before the white Jews. Their Hindoo complexion, and their very imperfect resemblance to the European Jews, indicate that they have been detached from the parent stock in India, many ages before the Jews in the West." There is therefore every probability that these white Jews will one day become as black as their sable brethren. This conjecture is in a great measure confirmed by the remark of Dr Smith, that the people of the United States, though sprung originally from many different nations of Europe, have now all an uniform cast of features and complexion.

We trust it will sufficiently appear from the facts which have been stated, that colour is a superinduced habit, and that no particular shade of it can be regarded as an inseparable adjunct of human nature; and when we observe that a white nation is never found under a fervid sun, nor a black one under a moderate temperature, it is impossible not to ascribe the difference of colour in the human species to the variations of climate, with the other accessaries which have been specied. There is no sudden transition of colour, no definable line of demarcation; but we observe the shades gradually deepening or mellowing, according as the countries are exposed to a violent, or a moderate heat. This completely destroys the argument, that a particular race different from the rest of mankind, was necessary to people the torrid zone; on the same principle it might be alleged that as many separate creations were necessary, as there are degrees of latitude from the equator to the poles.

There are indeed certain plants and certain animals, confined, by the constitution of their nature, to particular districts of the globe, and which cannot thrive beyond these limits. But nothing is more obvious than that the same species of men can exist, thrive, and multiply in every part of the known world, after their constitution has undergone that kind of transformation which is necessary to adapt them to their new situation. In fact, the very circumstance of man's being born without any natural covering or defence against the injuries of different climates, shows that he is intended as an inhabitant of all: and the Author of his nature has given him the power of adaptation, both in the resources of his own ingenuity, and in those insensible changes which are effected in conformity with the laws of nature, over which man has little or no controul. In the latter case, he enjoys no higher privilege than the bounty of heaven has conferred on various species of animals which are found indifferently in various climates; but have different colours and appearances according to the situations in which they are placed. Thus, hares, squirrels, and weasels, are white in northern latitudes, but brown or gray in milder climates. They are even found to vary their colours in the same country, according to the different degrees of heat. In Sweden, for instance, the hares are gray in summer, but perfectly white in winter. *Lepus apud nos*, says Linnæus, *æstate cinereus, hieme semper albus.* And in still higher latitudes, when the cold returns, both birds and animals assume the livery of winter.

Why then should we not expect to find the same variations in the skin of the human species? It is no anomalous appearance; it is the general law of nature, and we should have greater reason to be surprised did we find man an exception. It is impossible to assign any other cause for these varieties of colour than this, that such is the will of the Author of nature. The seat of colour in the human species has indeed been ascertained. It has been found that the skin consists of three *laminæ* or layers, the outer or scarf skin, the inner or true skin, and a substance interposed between them, which, from its nature and appearance, has been called *rete mucosum*. This is found to be the seat of colour, the outer and inner portions of the skin being found the same both in black and white people. This substance is found to be black in the Negro; reddish in the Mulatto; brown in the Gypsey; white, with a slight shade of red, in Europeans; and of a dead white in the Albino; whilst in all these instances, the *epidermis* or scarf skin is perfectly white. But this is only an additional fact; it is no explanation of the phenomenon.

If we can trust the accuracy of Barrere's observations, as stated in his *Dissert. sur la couleur des Negres*, we may perhaps go a little farther, and ascertain the *immediate* cause of the black colour. He supposes it to be owing to the colour of the bile, which, from several dissections of Negroes which he made in Cayenne, he affirms to be as black as ink; and as an effusion of the bile in white people tinges the skin of a yellow hue, the same effusion in Negroes will make the skin perfectly black. This is, no doubt, a curious fact; but why should the bile be constantly effused so as to tinge the skin in black people, whilst this happens only occasionally in the case of others? And were we to suppose, with Buffon, that both the bile and blood of Negroes are much blacker than in the case of other persons, and that the blackness of the skin is owing to these circumstances, this would only be removing the difficulty a step farther back; and it would still remain to be inquired to what this blackness of the blood and bile is owing. In the present state of our knowledge, we must be content to ascribe it, generally, to the heat of the sun, without being able to explain how the effect is produced.

But whatever may be the immediate or remote causes of the Negro complexion, we can discover, at least, a most beneficent *final* cause of such an appointment. It was long ago discovered by Dr Franklin, that black transmits heat more readily than any other colour. The subject has been investigated with much more minuteness by Mr Leslie and Count Rumford. The former discovered, by a set of most conclusive experiments, that hot water, in vessels of the same capacity, but of different colours, cooled fastest in those which were of a black or dark colour. And by taking a cubical vessel of tin, and coating one of the faces with lamp black, he found, by means of his very delicate differential thermometer, that much more heat was radiated or thrown off from the black side, than from the others which had been left clear, or which had been differently prepared. May we not consider, then, the black colour in the human species, which is only found in the most scorching climates, to be a wise expedient provided by the Author of our nature, for cooling the fever of the blood under the influence of a tropical sun?

We hope what has been said will be sufficient to account for the varieties of colour in the human species. But had we even been unable to trace so accurately the operation of heat on the human complexion, had we found black and white men, indifferently, under the various degrees of latitude, or of heat, we would see no more necessity for supposing a difference of species, than for applying the same expedient to solve the phenomenon of white and black sheep in the same flock, whose pedigree can be indisputably traced to the same ancestors. The varieties, in this case, are evidently accidental; though there is every probability that they might be perpetuated; and some have thought that the varieties in the human complexion are of the same kind. This might do well enough as an argument to make a stand upon, if others were wanting; but we think we have already stated others more philosophical, and of more decided efficacy in their operation.

It is certain, however, that there are some very remarkable *accidental* varieties in the human species. A very singular race of people is found on the Isthmus of Darien, whose colour is perfectly white, not, however, resembling the white skin of Europeans, but the dead white of the *Albino*. These people produce children of the same complexion and appearance with themselves, though there is every probability that they sprung originally from the copper coloured Indians of the Isthmus: because it is observed that this is sometimes the case still; and two copper-coloured parents sometimes produce an *Albino* child: nay, *Albinos* have often been born of perfect negroes. And it ought to be remarked, that *all the children of negroes are born white*, that the dark colour comes on in the course of a few months, and gradually deepens, in a course of years, into a glossy black. We have not, however, the same evidence of black children being ever produced from white parents, otherwise the hypothesis of an accidental variety giving rise to the negro race might be admitted; though we cannot see why this should not take place, more than the other variety. See Buffon's *Nat. Hist.* vol. iii. Smith's *Essay on the Variety of Complexion and Figure in the Human Species*. See Complexion for an account of the arguments for the other hypothesis. (*g*)
